INDEX

NAME INDEX

ott (W.), Machine Drawing and Design: a Textbook of Intermediate Standard for Engineering Students, 962
(Yoshio), The Wolf of Corea, 71
ous (J. E.), and R. Argaud, Formation of Adrenaline in the Suprarenal Gland, 682
ti (G.), Height of the Chromosphere in 1930, 1014
ham (J. J.), The late Mr. Herbert Tomlinson, F.R.S., 153
ard (C.), and A. Boutaric, Some Physical Properties of the Blood Serum in Lipoid Nephrosis, 315; and M. Doladilhe, The Physical Properties of the Blood Serum and of the Proteins separated from this Serum, etc., 555; and R. Arcand, The Physical Properties of the Serum Proteins and of the Hydropic Serosities in Lipoid Nephrosis, 646
erman (J. W.), [W. D. Bancroft, Catharine Gallagher, and], Optical Sensitisation, 846
ams (W. S.), elected President of the American Astronomical Society, 634
amson (J.), [death], 404
eew (N. W.), [N. S. Kurnakow and], Physico-chemical Study of the Gold-Copper Solid Solutions, 554
amon (Dr. A.), [death], 486
nslie (Capt. M. A.), Sir William Herschel's Mirrors, 1007
roldi (M.), Fossil Corallinaceæ from the Canaries (2), 735
den (Dr. H. L.), The Year's Progress in Astronomy, 801; Van Gent's Short Period Variable, 641
man (A. R.), The Meteorite Craters at Henbury, Central Australia, 977
nder (Dr. F. W.), Braille M[illegible] for teaching Electricity and Magnetism to the [illegible] 698
nder (H. G.), Bird Song and W[illegible] 549
xander (Prof. S.), Prof. H. Wildon Carr, 99; Purpose of a University, 385
xander (W. B.), Control of Prickly-Pear by the Cochineal Insect, 226
nko (N. F.), Diatoms growing on Stones on the Black Sea Littoral near Sebastopol, 422
(W. E.), Experiments in Wire-drawing (2), 594; W. Cartwright, Experiments in Wire-drawing (1), 4
(Prof. W. C.), Animal Aggregations: a Study in General Sociology, 940
(E. Patricia), and P. Smith, Selection of Skilled Apprentices for the Engineering Trades, 463
(F. J.), and R. B. Moore, Krypton and Xenon, 380
and Hanburys, Ltd., Insulin Therapy, 461
one (Dr. T. E.), [Dr. B. F. J. Schonland, and], Branching of Lightning, 794
n (A. H. G.), Supplement 6 to Trimen's "A Hand-Book to the Flora of Ceylon," 891
rof. T.), Reflection of Water Molecules at the id Surface, 72
(M.), Mercury Derivation of Divalent Bromo-[illegible]rols, 647
(H. R.), The Direct Determination of Nitrogen in ses, 845
R.), [A. Boutaric and], Experimental Researches the Adhesion of Lubricating Layers to Metals, 882
lingam (C.), [Prof. J. H. Orton and], Sex-change he Oyster, 273
Amoudruz (G.), [A. Jayet and], The Discovery of Magdalenian Deposits near Frangy (Haute Savoie), 1087
Amstutz (A.), The Petrographic Character of Banks Island in Melanesia, 734
Anderson (H. V.), and K. C. Chesley, X-Ray Analysis of Slate, 1043
Anderson, [Newton and], Respiration of Wheat at Low Temperature, 970
Andrade (Prof. E. N. da C.), The Viscosity of Liquids, 835
Andrew (Prof. J. H.), appointed Professor of Metallurgy in Sheffield University, 975
Andrews (H. E.), Catalogue of Indian Insects. Pt. 18, 867
Andrews (J.) and others; edited by Prof. R. Hegner and J. Andrews, Problems and Methods of Research in Protozoology, 395
Andrews and Bacon, Production of High Vacua, 121
Andruetto (G.), The Intrinsic Equations of Elastic Equilibrium, 734
Annequin (R.), [L. Bert and], A New Method of Synthesis of Einnamic Aldehyde and its Homologues substituted in the Nucleus, 125
Antoniani (C.), Behaviour in an Electric Field of Colloidal Humic-mineral Complexes, 735
Appleton (Prof. E. V.), Polarisation of Downcoming Wireless Waves in the Southern Hemisphere, 1037; and G. Builder, Wireless Echoes of Short Delay, 918
Arber (Dr. Agnes), Structural Features of the Cruciferous Flower, 1043
Arcand (A.), [C. Achard, A. Boutaric, and], The Physical Properties of the Serum Proteins and of the Hydropic Serosities in Lipoid Nephrosis, 646
Archangelskii (A.), and D. Perkin, Origin of the Ferrous Deposits in the Lipetsk Area, 163
Arditti (G.), The Oxidation of Paraffin Oil, 882
Argaud (R.), [J. E. Abelous and], Formation of Adrenaline in the Suprarenal Gland, 682
van Arkel (A. E.), und J. H. de Boer, Deutsche, von den Verfassern autorisierte Ausgabe von L. Klemm und W. Klemm, Chemische Bindung als elektrostatische Erscheinung, 816
Arkell (Dr. W. J.), [Dr. K. S. Sandford and], Palæolithic Man and the Nile-Faiyum Divide: a Study of the Region during Pliocene and Pleistocene Times, 287; [J. A. Douglas and], The Stratigraphical Distribution of the Cornbrash (2), 125
Arkwright (J. A.), and others, A System of Bacteriology in Relation to Medicine. Vol. 6, 888
Armellini (G.), The Horizontal Diameter of the Sun in 1929 and 1930, 1014; The Theory of the Variability of the Family of Mira Ceti, 646
Armstrong (Dr. E. F.), Paper Making, 949; Problems of the Mineral Industry, 508
Armstrong (Prof. H. E.), Cosmic Evolution and Earthly Needs, 761; The Dyestuff Industry, 542
Armstrong (J. I.), awarded a Beit Fellowship for Scientific Research, 161
Arnot (Dr. F. L.), appointed Lecturer in Natural Philosophy in the United College, St. Andrews, 81; Diffraction of Electrons, 799
Arnulf (A.), La mesure des rayons de courbure des surfaces sphériques employées en optique, 323

Arrivaut (G.), Action of Arsenic Chloride upon Nickel, 82
Ashbridge (N.), Acoustical Problems of Broadcasting Studios, 844
Ashcroft (E. W.), Faraday, 323
Ashworth (Dr. J. R.), The Specific Heat of Ferromagnetics and Ewing's Model of the Magnetic Atom, 1003
Askania-Werke A.-G., Photographic Vibrograph, 460
Askew (F. A.), Miss H. M. Bruce, Dr. R. K. Callow, J. St. L. Philpot, and T. A. Webster, Crystalline Vitamin D, 758
Aston (Dr. F. W.), Atomic Weights deduced from Mass-spectra, 460; Constitution of Lithium, 149; Constitution of Thallium and Uranium, 725; New Isotopes of Strontium and Barium, 221; The Unit of Atomic Weight, 731
Atkins (Dr. W. R. G.), Accuracy obtainable with Gas-filled Photoelectric Cells, 550; Radiation and Life, 199; The Penetration of Light through Successive Layers of Tissue Paper, 545; The Treatment of 'Gapes' in Chickens, 585; and Florence A. Stanbury, Illumination and Tree Growth, 191
Atkinson (Ll. B.), The Mechanical Aspects of Electricity (Thomas Hawksley Lecture), 865
Atkinson (Dr. R. d'E.), Atomic Synthesis and Stellar Energy, 194
Van Aubel (Prof. E.), Diamagnetism of Liquid Mixtures, 455; Rotatory Magnetic Polarisation, 1004
Auden (Dr. H. A.), and Dr. W. P. Joshua, Saccharification of Wood, 1045
Audubert (R.), The Rôle of Water in Photovoltaic Cells, 466; and J. Roulleau, The Rôle of the Phenomena of Photoconductance in the Photovoltaic Effect, 555
Auger (P.), and C. Lapicque, Variation in the Spectrum of the Sensibility of Cuprous Oxide Cells, 646
Aughtie (Dr. F.), A Remote Electrically Recording Accelerometer with particular reference to Wheel-impact Measurements, 918; A Remote Electrically Recording Load-gauge for Wheel-impact Measurements, 918
Austin (H. O.), Insulation of Overhead Transmission Cables, 416
Aveling (Dr. F. A. P.), Conferment upon, of the title of Professor, 975
Ayling (Jean), The Behaviour of Young Children, 777
Ayyar (T. V. Ramakrishna), Control of Prickly-Pear by the Cochineal Insect, 837

Baade (Dr. W.), A New Cluster of Faint Nebulæ, 641
Baba (Kikutaro), A supposed Primitive Gill-less Nudibranch, 728
Babička (J.), Polarographic Analysis with the dropping Mercury Cathode of Extracts from Plant Tissues, 1013
Bacon, [Andrews and], Production of High Vacua, 121
Badami (J. S.), [Prof. A. Fowler and], Spectrum of the Hydrogen-nitrous Oxide Flame, 881; [Dr. K. R. Rao and], Resonance Spectrum of Hydrogen, 585; and Dr. K. R. Rao, The Structure of the Spectrum Se III, 496
Badger (Prof. W. L.), and Prof. W. L. McCabe, Elements of Chemical Engineering, 622
Badley (J. H.), The Will to Live: an Outline of Evolutionary Psychology, 954
Badoche (M.), [C. Dufraisse and], Researches on the Dissociable Organic Oxides, 422, 503
Bailey (C. R.), and A. B. D. Cassie, Infra-Red Absorption Spectrum of Carbonyl Sulphide, 637
Bailey (Prof. E. B.), Representation of Crystal Structure, 869
Bailey (Mrs. F. M.), awarded the Brewster-Medal of the American Ornithologists' Union, 998
Bailey (Dr. G. H.), and H. W. Bausor, Chemistry for Matriculation. Third edition, 173
Bailey (Dr. K. C.), The 'Lapides palmati' mentioned in the "Historia Naturalis" of the Elder Pliny, 672
Bailey (Prof. S. I.), [death], 13
Bailly (O.), and R. Netter, The Isolation of Carotene from the Suprarenal Glands, 1086
Bainbridge (K. T.), Isotopes of Lithium, Sodium, and Potassium, 876
Baird and Tatlock (London), Ltd., Analytical Reagents, Standards, and Tests, 65
Baker (J. R.), Spermicidal Power of Chemical Con ceptives, 119
Baker (Prof. R. H.), Astronomy: an Introduction, 56
Baker (R. T.), On a Fossil Timber from the Sydney bour Colliery, 806
Baker (W.), A Two-Dimensional Space Lattice? 1078
Bakker (Dr. C. J.), [E. Segré and], Zeeman Effect Forbidden Line, 1076
Balavoine (P.), A Formula for the Determination of Alcoholic Strength of Brandy, 279; The Analy Characters of Caramel regarded as a Colouring M for Food, 83
Bald (J. G.), [G. Samuel and], *Thrips tabaci* as a V of Plant Virus Disease, 494
Baldet (F.), The Raffety Bands and the Spectra of Co 234
Baldwin (Prof. J. Mark), Gift to the Edward Bag Poulton Fund of Oxford University, 975
Balfour-Browne (J. W. A. F.), elected a Frank Sm Student in Zoology at Gonville and Caius Coll Cambridge, 768
Ballantyne (W. H.), The Cost of Patent Litigation, 7
Balls (Dr. W. L.), and others, Operation of the Control Law upon the Pedigree of Cotton Se Developments of the Existing System for Seed Su of Cotton in Egypt, 766
Balme (G.), [R. de la Boulaye and], Velocity of Propaga of Musical Sounds, 646
Bancroft (W. D.), and J. E. Rutzler, jr., Revers Coagulation in Living Tissue, (2) 280, 1014; G. H. Richter, (3) 423, (4) 846; J. W. Ackerman, Catharine Gallagher, Optical Sensitisation, 846; S. F. Whearty, jr., Activation by Charcoal, 280
Banting (Dr. F. G.), awarded the Flavelle Medal of Royal Society of Canada, 275
Barbieri (G. A.), Molybdo-octocyanides, 647; Rhodi Compounds, 683
Barcroft (Prof. J.), [Dr. R. Lemberg, Dr. D. Keilin, and Uteroverdin, 967
Bardet (J.), [C. Levaditi, A. Tchakirian, A. Vaisman, and The Distribution of Gallium in the Organism, 466
Barksdale (J. D.), [Dr. J. A. Cushman and], Tertiar Foraminifera, 1080
Barnard (Dr. F.), [death], 666
Barnard (J. E.), and W. J. Elford, The Causative Organis in Infectious Ectromelia, 917
Barnell (H. R.), appointed Frank Smart University Student in Botany in Cambridge University, 844
Barnes (Dr. A. S.), appointed Dean of the Faculty Medicine of Birmingham University, 80
Barnes (Bishop E. [illegible]), The Evolution of the Universe, 7
Barnett (Dr. [illegible]), appointed Curator of Reptiles of t Zoological Society's Gardens, 1036
Barnett (Dr. M. A. F.), Radio Observations during a So Eclipse, 381
Barnett (Prof.), A New Electron-Inertia Effect, 549
Barnitt (J. B.), and R. H. Heilman, Heat Insulation o Furnaces, 971
Baron (C.), C. Boulanger, and R. Le Grain, Petrol-alcohol-benzene Mixtures, 163
Barr (Prof. A.), [death], 266; [obituary article], 294
Barr (Dr. G.), A Monograph of Viscometry, 947
Barrett (B. H.), [Prof. J. W. Gregory and], Gener Stratigraphy, 945
Barrett (C.), The Habits of *Megascolides australis*, 669
Barrett (Sir James W.), Nationalism and Science in Chin 1035; Preservation of the Australian Flora and Fau 1041
Barritt (N. W.), Cotton Growing in Egypt, 1001
Barry (T. H.), Oil from Malayan *Aleurites Montana* the Properties of Hong Kong Oil, 1086
Bartlett, jr. (J. H.), Isotopic Displacement in Hyp Structure, 408
Bartoszewiczowna (Mlle. E.), [W. Swietolawski and plication of the Adiabatic Microcalorimeter Determination of the Heat of Adsorption and of isation, 126
Barve (P. M.), [Dr. B. N. Desai and], Coagulat Colloids by Electrolytes, 907
Bastow (S. H.), and F. P. Bowden, On the Co Smooth Surfaces, 881

Basu (P. C.), [Dr. B. S. Guha and], Human Skulls and Bones from the Naga Hills, 762
Bate (A. E.), The Bottle-Pipe Resonator, 270
Bates (J. R.), [G. E. Kimball and], The Band Spectrum of AsH, 969
Bateson (G.), elected a Fellow of St. John's College, Cambridge, 768
Bather (Dr. F. A.), Echinoderm Larvæ, 417
Baur (Dr.), Plant Breeding in Germany, 975
Bausor (H. W.), [Dr. G. H. Bailey and], Chemistry for Matriculation. Third edition, 173
Beadle (G. W.), Supernumerary Cell Divisions in Maize, 191
Beadle (L. C.), awarded a Grant from the Balfour Fund of Cambridge University, 880
Bearden (Dr. J. A.), Absolute X-Ray Wave-lengths, 156
Beattie (Prof. J. M.), Foot-and-Mouth Disease Research, 765; Studies in Immunity, 888
Beauvais (G.), [C. Gutton and], Oscillators with very Short Waves, 1013
Becke (Prof. F.), [death], 13
Beckett (H. E.), [A. F. Dufton and], Measurement of Ultra-Violet Radiation, 223; Unusual Lightning, 189
Becquerel (J.), and L. Matout, The Decomposition of the Absorption Bands of Xenotime by a Transverse Magnetic Field, 466
Bedford (Lieut.-Col. Sir Charles), [death], 143; [obituary article], 178
Beebe (Dr. W.), The Bermuda Oceanographic Expedition, 406

Æneas, Elements of the Trojan Planet, C. J. Krieger, 764
Aerobacter, Bacteria belonging to the Sub-genus, M. Grimes and A. J. Hennerty, 162
Aerodynamics, Elementary Applied, T. G. Whitlock, 654
Aeroplane: Flight: between Australia and England, Record, J. A. Mollison, 266; Round the Earth on a 'Small Circle' Course, Post and Gatty, 60; Manual, The Light, F. D. Bradbrooke, 961; Speed Records by Flight-Lieut. J. N. Boothman and Flight-Lieut. G. H. Stainforth, 490; Survey of Peru, 172
Aeroplanes and Mosquitoes, 1072
Aerosols: Charged, and Ball Lightning, W. C. Reynolds, 584; Highly Charged, A Curious Phenomenon shown by, W. Cawood and H. S. Patterson, 150; Properties of, S. C. Blacktin, 968
Africa: Botanical visit to, Hutchinson, 218; Living, a Geologist's Wanderings through the Rift Valleys, Prof. B. Willis, 87; in Transition, Lord Lugard, 730; Native Administration in, 685; View, Prof. J. S. Huxley, 87
African: Languages and Cultures, International Institute of, Grant to the, by the Rockefeller Foundation, 265; Prehistory, *Homo sapiens* and, E. J. Wayland, 1003; Settlement and the Origin of Rift Valleys, Prof. J. W. Gregory, 87
Agar-liquefying Bacteria, Distribution of, H. Nicol, 1041
Agricultural: Botany, National Institute of, Policy of the, Prof. Engledow, 184; Entomology, A Textbook of, Dr. Kenneth M. Smith; Dr. A. E. Cameron, 943; Devices in Germany, New, R. Borlase Matthews, 297; Research Council, Sir William Dampier appointed Secretary of the, 299
Agriculture: and Physics, 391; International Aspects of, 597; Science and, in New Zealand, 981; The Changing Outlook in, Sir John Russell, 1027; The International Institute of, Dr. A. Hobson, 737; The Waste Products of: their Utilization as Humus, A. Howard and Yeshwant D. Wad, 854
Agriculturists, British and Danish, Exchange of, 181
Air: and Gases, Flow and Measurement of, A. B. Eason. Second edition, 654; Condensation of, into Liquid, Prof. E. O. von Lippman, 666; Currents: Control of Humidity of, Dr. P. A. Buxton; Dr. W. H. J. Vernon and L. Whitby, 837; of Different Humidities, A Method of obtaining, Prof. J. B. Seth, 638; in the Tracheoles of some Terrestrial Insects, Extent of, Dr. V. B. Wigglesworth, 917; Oxygen, and Nitrogen, The Specific Heats of, from 20° C. to 370° C., P. S. H. Henry, 1049; Pollution at Pittsburgh, H. B. Meller, 307; -pressures upon a Bird's Wing, Lieut. R. R. Graham, 119; Warm and Cold Saturated, Mixing of, K. Hidaka, 911
Aircraft Observation, Determination of Position in High Latitudes, with particular reference to, C. J. Stewart, 212
Airships *R* 38, *R* 101, and others, Causes of the Loss of, A. Krylov, 683
Air Speed Record, New World, Flight-Lieut. G. H. Stainforth, 611
Aitken Condensation Nuclei, A. R. Hogg, 908
AK Herculis, The Variable Star, J. Wasiutynski, 1081
Alchemical Apparatus, Prof. J. R. Partington, 118
Alchemie, Entstehung und Ausbreitung der, Prof. E. O. von Lippmann. Band 2: Ein Lese- und Nachschlage-Buch, 774
Alchemist, The Travels of an: the Journey of the Taoist Ch'ang-Ch'un from China to the Hindukush at the Summons of Chingiz Khan. Recorded by his Disciple, Li Chih-Ch'ang. Translated with an Introduction by A. Waley, 509
Alchemy, History of, Dr. E. J. Holmyard, 774
Alcohol: and Behaviour, Prof. Sydney Smith, 630; Combustion of, by the Pœcilotherm, M. Nicloux, 682
Alcoholic Fermentation: Action of various Halogen Derivatives on, P. Cayrol, 770; The Kinetics of the, J. Medvedev, 163
Alcohols, Oxidation of the, by the Acetic Ferments, H. Quéré, 770
Aldehydes, The Ozonation of, and the Theory of Active Molecules, E. Briner, A. Demolis, and H. Paillard, 235
Algebra: A School, as far as the Advanced Course in the School Certificate Stage, A. M. Bozman, 1061
Alginic Acid: On, its Mode of Occurrence and its Constitution, T. Dillon and Annie McGuinness, 162
Alkaline Diacid Phosphates, Action of Heat on the, L. Hackspill and R. Lauffenburger, 682
'All or None': a Question of Nomenclature, W. W. Waller, 70
Allantoin: Application of the Quantitative Spectrophotometric Analysis of, to the Blood of some Mammals and to the Seed of numerous Plants, R. Fosse, A. Brunel, and P. E. Thomas, 421; The Quantitative analysis of very small quantities of, at High Dilutions, R. Fosse, A. Brunel, and P. E. Thomas, 315
Alloys, New High Permeability, G. W. Elmen, 764
Alpine Plants, The Diurnal Course of Transpiration of Two, F. Chodat and Suzanne Kann, 126
Alternating Current Supply, Control of Frequency of, 330

Aluminium: Sand-castings, Unsoundness in, D. Hanson and I. G. Slater, (1), (2), 502; -Silicon Alloys, The Macro-etching of, Dr. W. Hume-Rothery, 503; The Toxic Power of, compared with that of Iron, Nickel, and other Metals, G. Bertrand and P. Serbescu, 466

American: Astronomical Society, Prof. W. de Sitter elected an Honorary Member and W. S. Adams President of the, 634; College Sport, Current Development in, 197; Educational Progress in 1930, 420; Indian, Physical Anthropology of the, Prof. W. E. Le Gros Clark, 740; Ornithologists' Union, Elections in connexion with the, 998; Universities, Doctorates in Science conferred by, 501

Amides, Velocities and Heats of Saponification of the, E. Calvet, 235

Aminophenylpyrazoles, Diazotisation of, Prof. J. Reilly, B. Daly, and P. J. Drumm, 162

Ammeter for Measuring very Minute Alternating Currents, An, P. J. Kipp and Zonen, 183

Ammonium, Solid, Group Rotation in, and Calcium Nitrates, F. C. Kracek, S. B. Hendricks, and Dr. E. Posnjak, 410

Amorphous Carbon, The Critical Increment of the Absorption of Hydrogen on, at 400°-520° C., Dr. F. E. T. Kingman, 272; Silica and Crystallised Quartz, The Double Refraction produced by the Compression of, and its Dispersion in the Ultra-Violet, G. Bruhat and J. Thouvenin, 1050

Ampère, A. M., the house of, presented to the French Society of Electricians, 111

Amulets and Superstitions, Sir E. A. Wallis Budge, 204

Amylase, Action of Ultra-Short Electromagnetic Waves (2-3 metres) on, G. Mezzadroli and E. Vareton, 43

Anchusa, Cytology of, and its Relation to the Taxonomy of the Genus, S. G. Smith, 493

Anemusite (with reference to Pacifiles of Barth), D. Beliankin, 422

Angara, Influence of Lake Baikal on the Summer Thermic Régime of the River, G. Vereschagin, 467

Anhydrides, Action of, upon Metals, M. Lemarchands and H. L. Roman, 163

Animal: Aggregations: a Study in General Sociology, Prof. W. C. Allee, 940; Biology, Principles of, Prof. L. Hogben, 242; Ecology and Evolution, C. Elton, 243; Genetics, Imperial Bureau of, Bibliographies of the, 865; *Quarterly Bulletin* of the, 866; Year Book, The, Capt. C. W. Hume, 102

Animals under Human Control, Variation of, 934

Anisotropy due to Flow in Cellulose Sols, J. M. Preston, 796

Annual Tables of Constants and Numerical Data for Chemistry, Physics, Biology, and Technology, 662

Antarctic: Alcyonaria, Madreporaria, and Antipatharia, Sir J. Arthur Thomson and Miss Nita Rennet, 71; Research Expedition, The British Australian New Zealand, 79

Anthocyanins: Constitution of, G. M. Robinson and Prof. R. Robinson, 413; Synthesis of, Robinson and others, 912

Anthropological Bulletins of the Zoological Survey of India, 756

Anthropologie, Leitfaden der, Dr. K. Saller, 624

Anthropology: and Native Administration, 86; in Nigeria, P. Amaury Talbot, 285; Training of Colonial Probationers in, Col. T. C. Hodson, 458

Antibodies, A Theory of the Constitution of, H. Vincent, 1049

Antimony Electrode, The, as a Means for *p*H Measurements, A. C. Leeman, 682

Anti-Neuritic Vitamin, Seidell and Birckner, 229

Anura, Vascular System of the, Abnormalities of the, Dr. C. H. O'Donoghue, 42

Appalachians, Northern, Building of the, Prof. C. Schuchert, 227

Apples in Storage, Nitrogen Content of, Pilling and Pearsall, 549

Apprentices for the Engineering Trades, Selection of Skilled, E. Patricia Allen and P. Smith, 463

Aquaria, The Sunless Keeping of, 406

U Aquilæ, Variation of the Radial Velocity of, G. Tiercy, 682

Arabia, Alarms and Excursions in, B. Thomas, 956

Araucanos, The Eggs of, C. A. Finsterbusch, 697

Archæological Societies, Congress of, Address to the, Sir Charles Peers, 900

Archæologist, a Great, Unofficial Moments of, S. R. K. Glanville, 131

Archæology and Surveying in Southern Rhodesia, 500

Arcs, Island and Mountain, Curvature of, Prof. T. Terada, 498

Arctic: and Adjacent Regions, Some General Structural Features of the, O. Holtedahl, 125; Institute of the U.S.S.R., Bulletin of the, No. 5, 219

Argentine Republic, The, and the Transmission of Rhythmic Time Signals, 217

Aristotle, The Works of, Translated into English. Physica, by R. P. Hardie and R. K. Gaye, 396

Armadas of the Sky: the Problem of Armaments, P. Murphy, 963

Aromatic Substitution Products with Fluorine, W. D. Bancroft and J. E. Whearty, Jr., 280

Arsenic Chloride, Action of, upon Nickel, G. Arrivaut, 82

Art, Works of, Scientific Methods applied to the Examination and Preservation of, Conference on, 147

Ascidians, New North and South American, Dr. W. G. Van Name, 71

Asebotoside (Asebotine): The Constitution of, its Identity with Phlorizoside (Phlorizine), M. Bridel and Mlle. A. Kramer, 978

AsH, The Band Spectrum of, G. E. Kimball and J. R. Bates, 969

Asiderite Meteorite, Fall of an, in the Extreme South of Tunis, A. Lacroix, 643

Astronomers and Observatories, New List of, Prof. P. Stroobant and others 73

Astronomy: A New History of, Dr. J. K. Fotheringham, 986; an Introduction, Prof. R. H. Baker, 563; for all, 615; Spherical, Text-Book on, Prof. W. M. Smart, 207; The Year's Progress in, Dr. H. L. Alden, 801

Astrophysical Formula, An, P. Rossier, 734

Astrophysik auf atomtheoretischer Grundlage, Prof. S. Rosseland, 615

Atlantic: Foraminifera, J. A. Cushman, 798; South, Velocity of Deep Currents in the, G. E. R. Deacon, 267

Atlas céleste, E. Delporte 690

Atmospheric: Electric Fields, Utilisation of, A. Brasch and F. Lange, 380; Large Ions, Mobilities of, R. K. Boylan, 1013; Ionisation, Prof. J. J. Nolan and Dr. P. J. Nolan, 971; Motion, Horizontal, The Energy of, Sir Napier Shaw, 226; Pollution, Prevention of, 649

Atolls, The Formation of, 206

Atom, Excited, Electron Exchange Phenomena in the, Prof. R. Whiddington and J. E. Roberts, 966

Atomic: Hydrogen Occluded in Iron Nitride, Shun-ichi Satoh, 457; Synthesis and Stellar Energy, Dr. R. d'E. Atkinson, 194; Systems and Optical Activity, Spatial Arrangements of; Methods, Results, and Problems of Precise Measurements at High Temperatures; The Constitution and Structure of Ultramarines, F. M. Jaeger, 852; Weight, The Unit of, Dr. F. W. Aston, 73[illegible]; Weights Deduced from Mass-Spectra, Dr. F. W. Aston, 460

Atoms: and Molecules as Fitzgerald Oscillators, Sir C. V. Raman, 795; at Collision, On the Transfer of Energy between, O. K. Rice, 83; Wave-Mechanical Models of, H. E. White, 228

Atropine, Action of, in Counteracting the Effects of Pituitrin and of Pilocarpine Injected into the Cerebral Ventricles, H. Cushing, 280

Aurora: Polaris, Audibility of the, H. U. Sverdrup, 457; The Nature of the, Prof. J. Kaplan, 191

Australasia: The Gasteromycetes of, G. H. Cunningham (12), 595; (13), 918

Australia: a Female Aboriginal Skull found in the Jervois Ranges, Prof. F. Wood Jones, 440; An American Collecting Expedition to, 63; Commonwealth of: Official Year Book of the, No. 23, 1930. Prepared by C. H. Wickens. Editor: J. Stonham, 514; W. S. Watt appointed Meteorologist to the, 634; Eastern, Granites of, Prof. E. W. Skeats, 307; Need for the Protection of Mammals in, 935; Taxes on Books in, 900; Vanishing Life of, 425

Australian: Aborigines, Food of, C. Daley, 762; Council for Scientific and Industrial Research, Annual Report of the, 62; Diptera, J. R. Malloch, 595, 918; Flora and Fauna, Preservation of the, Sir James W. Barrett, 1041; Fossil King-Crabs, Two New, F. Chapman, 683; Fungi, Catalogue of, 635; National Research Council, Proposed changes in Constitution, etc., 611; Zebra-finch, Pugnacity of the, Dr. E. Hopkinson, 866
Austria: Distribution of Declination in, at the Epoch 1930.0, A. Schedler and M. Toperczer, 43; Faraday and, Prof. K. Przibram, 351; The Sword Dances of, Dr. R. Wolfram, 823
Auto-frettage, and the Theory of Strain, 49
Avoleum, a Preparation made from Mammalian Liver, British Drug Houses, Ltd., 147
Axolotl, Regeneration of the Extremities in the, under the Influence of X-Rays, E. Litchko, 127
Azide Group, Structure of the, T. C. Sutton, 872
Azides: Structure of the, from their Electric Dipole Moments, L. E. Sutton, 639; Structure of the, Dr. E. Bergman and W. Schutz, 1077
Azopyrrole Blacks, A. Quilico and M. Freri (3), 595

B. tumefaciens, Factors exciting Increase of Vegetal Neoplasms by, V. Rivera, 806
Babirusa of Celebes, The, 697
Bacille Calmette-Guèrin Vaccine, The, A. S. Griffith, 145
Bacteria, Luminous, The Combined Action of Metals and X-Rays on, E. Stern, 503
Bacterial: Flora of Certain Fish, G. Cannicci, 735; Plant Pathogens, Manual of, Charlotte Elliott, 953
Bacteriology in relation to Medicine, A System of. Vol. 6, J. A. Arkwright and others, 888
Bacteriophage, The, and its Clinical Applications, Prof. F. d'Herelle. Translated by Prof. G. H. Smith, 431
Bacterium granulosa of Noguchi in its relations with the Etiology of Trachoma, The, C. Nicolle and U. Lombroso, 81
Balun Bidai, I. H. N. Evans, 762
Band Spectra, Complicated, Analysis of, with the Aid of Magnetic Rotation Spectra, Prof. R. W. Wood and G. H. Dieke, 545
Banks Island, Melanesia, The Petrographic Character of, A. Amstutz, 734
Barbituric Derivatives, Some Reactions of Certain, J. Bougault and J. Guillou, 770
Baridiinæ, On (Curculionidæ), mostly from New Guinea, A. M. Lea, 279
Barium: Hydride, Bands in the Spectrum of, Dr. A. Schaafsma, 1042; Nitrate in Nitric Acid, The Equilibrium in Solutions of, at the Temperatures of 0° and 25°, P. I. Tolmatchev, 163; Strontium and, New Isotopes of, Dr. F. W. Aston, 221
Barley and its Wort, Nitrogen Contents of, L. R. Bishop, 308
Bathurst Senkungsfeld, The, C. A. Sussmilch, 467
Bathyliths, Notes on, and Some of their Implications, W. R. Browne, 806
Bats, Three New, of the genera *Pteropus*, *Nyctimene*, and *Chearephon*, from Melanesia, E. Le G. Troughton, 387
Bauxite in the Upper Sann Valley, Genesis of, E. Dittler and O. Kuhn, 467
Bavenda, The, Dr. H. A. Stayt, 614
Beagle, The Voyage of the, 1831–1836, 1065, 1068
Bedford College for Women, Opening of New Building, 14
Beetroot, The Sapogenin of, V. Prelog, 127
Beilstein's Handbuch der organischen Chemie, A Brief Introduction to the Use of, Prof. E. H. Huntress, 136
Beit Fellowships for Scientific Research, Sir Campbell Stuart appointed Chairman and Sir Alfred Beit a Trustee of the; award of Fellowships to W. H. Wheeler and J. I. Armstrong, 161
Belfast: Naturalists' Field Club, S. A. Bennett awarded the Club Medal, 757; Queen's University of, Dr. J. S. Young appointed Musgrave Professor of Pathology, 804
Bellerophons, Carboniferous, Dr. J. Weir, 497
Benzene: and Toluene, Raman Spectra of, L. E. Howlett, 796; into Methane, The Transformation of, A. Mailhe and Creusot, 422; Nitrobenzene and, Melting Points of, Prof. I. Masson, 726
Bergey's Manual of Determinative Bacteriology: a Key for the Identification of Organisms of the Class Schizomycetes, D. H. Bergey, and others. Third edition, 6
Bermuda Oceanographic Expedition, The, Dr. W. Beebe, 406
Berne University, conferment of Honorary Doctorates on Sir Charles Sherrington and Prof. H. Cushing, 681
Beryllium Ferrite and the Ferric Oxide arising from its Decomposition, H. Forestier and M. Galand, 978
Betelgeux, The Variability of, B. W. Kukarkin, 764
Bibliography of Science, Classification for, Dr. S. C. Bradford, 268
Bichler and Napieralski, The Synthesis of, M. Decker, 467
Biochemistry in America, 90
Biocolloidologie, Traité de, W. Kopaczewski. Tome 1: Pratique des colloïdes. Deux. édition. Fasc. 3: Mésures capillaires et électriques, 852
Biologischen Arbeitsmethoden, Handbuch der, Herausgegeben von Prof. E. Abderhalden: Lief. 331. Abt. 9. Teil 4, Heft 4 (Schluss), 396; Lief. 346. Abt. 9. Teil 7, Heft 1, 431
Biology: as a Real Profession, Plea for, Dr. H. Martin Leake, 666; A Short History of, A General Introduction to the Study of Living Things, Dr. C. Singer, 132; and Civilisation, Dr. H. H. Dale, 897; Historical Aspects of, Prof. L. Hogben, 132; Progressive, Sir Frederick Gowland Hopkins, 923
Bird: Migration in Switzerland, Dr. K. Bretscher, 676; Migrants at the Rossitten, D. Yorke, 440; Sanctuaries in the Royal Parks of England, Report on, for 1930, 1071; Song and Weather, H. G. Alexander, 549
Birds: Migration of, Dr. J. Grinnell, 329; of the Galapagos Islands, H. S. Swarth, 762; Speed of Flight of, T. H. Harrisson, 586
Birmingham University: award of Doctorates; Dr. A. S. Barnes appointed Dean of the Faculty of Medicine; Dr. R. H. Hopkins appointed Adrian Brown Professor of Brewing; R. D. Lockhart, Professor of Anatomy; and P. Gray and D. Richards, Resident staff Tutors of Adult Education; Prof. A. M. Carr-Saunders to be Muirhead Lecturer for another year, 80; S. Lees appointed Professor of Mechanical Engineering, 278; Ore-dressing Laboratory of the Mining Department of, Opening of the, 1068; Conferment of Honorary Degrees, 1069
Birth Control, Ministry of Health Circular on, 298
Birthdays and Research Centres, 41, 125, 162, 198, 234, 278, 314, 385, 420, 465, 502, 553, 594, 645, 681, 733, 768, 805, 881, 916, 976, 1012, 1049, 1085
Bismuth, Double Sulphates of, with Alkali Metals (2), L. Malossi, 1050
Bison, European, in the Caucasus, 633
Bitumen of the Urgonian Limestone and the Molasse of Pyrimont (Ain), The, J. J. Pittard, 734
Black: Sea Sprat, The, L. Berg, 770; Spur Area (Healesville), Geology and Petrology of the, A. B. Edwards, 467
Blepharoceridæ of Japan, Sirô Kitakami, 640
Blind, National Institute for the, Report for Year ending March 31, 1931, 868
Blood: of Aquatic Animals, The Composition of the, and its Bearings upon the possible Conditions of Origin of the Vertebrates, Prof. W. J. Dakin, 66; Serum, The Physical Properties of the, and of the Proteins separated from this Serum by the Acetone Method, etc., C. Achard, A. Boutaric, and M. Doladilhe, 555
Bopyrid Parasite, A New, from the Coast of N.S.W., Prof. W. J. Dakin, 595
Boric Acid and Alumina, Separation and Estimation of, Malaprade and Schmoutka, 315
Boron, Crystallised, L. Hackspill, A. Stieber, and R. Hocart, 1013
Botanical: Congress, Fifth International, Cambridge, 16–23 August 1930. Report of Proceedings. Edited by F. T. Brooks and Dr. T. F. Chipp, 778; Society and Exchange Club of the British Isles, Report for 1930, 668

Botany, The Advancement of, Prof. T. G. Hill, 538, 780
Bottle-Pipe Resonator, The, A. E. Bate, 270
Bovine Tuberculosis and the Pasteurisation of Milk, 36
Boys's Soap Solutions, Effect of Light on the Surface Tension of, Prof. L. D. Mahajan, 496; Dr. P. Lecomte du Nouy, 674
Braconid Parasite, Polyembryony in a, H. L. Parker, 190
Bradford Technical College, *Journal of Research* of the, 845
Braille Models for Teaching Electricity and Magnetism, Dr. F. W. Alexander, 698
Brain: and Mind, A. Lynch, 954; Mind, and the External Signs of Intelligence, Dr. B. Hollander, 815
Brandy, Alcoholic Strength of, A Formula for the Determination of the, P. Balavoine, 279
Brass, High-strength, The Failure of a, J. E. Newson and A. Wragg, 503
Bread: a Collection of Popular Papers on Wheat, Flour, and Bread, H. Snyder. With Biographical Sketch by A. L. Winton, 953
Breeding from Colour Varieties, J. C. Laidlay; D. Seth-Smith, 379
Bretons et Anglais aux V^e et VI^e siècles, F. Lot, 61
Brewster Medal of the American Ornithologists' Union, award of the, to Mrs. F. M. Bailey, 998
Bridge Piers, The Profile of, A. Signorini, 43
Brighter Biochemistry, No. 8, 490
Brinell Indentations in Cold-rolled Metal, The Diameter Measurement of Certain, H. O'Neill, 595
Britain and World Trade: Quo Vadimus and other Economic Essays, A. Loveday, 955
British: Association: Centenary Meeting of the, Programmes of Sections, 230; The Faraday and, Centenaries, 328; Centenary Meeting, The, 483; Centenary Celebration at Liverpool, 520; Centenary Meeting, Presidential Address, 521; Summaries of Addresses of Presidents of Sections, 530-540; Commemorative Service at Liverpool Cathedral, 572; Sectional Meetings and Discussions, 573; Sir Alfred Ewing elected President of Meeting for 1932, 575; a Retrospect, 1831–1931, O. J. R. Howarth. Centenary (second) Edition, 687; London and the, 687; Sidelights on the, 982; Australian New Zealand Antarctic Research Expedition, The, 79; of Commercial Seed Analysts, Annual Meeting of the, 265; *Birds*, August, 332; Chemical Industry, A History of the, Dr. S. Miall, 45; Coal Trade, Influence of Modern Hydro-Electric Power Development on the, Dr. Brysson Cunningham, 397; Coleopterous Fauna, Additions to the, H. St. J. Donisthorpe, 155; Douglas Fir, Timber of the, B. J. Rendle, 971; Empire Cancer Campaign: Eighth Annual Report, 664; Gift to the, by Sir William A. Morris, 440; Engineering Standards Association, Reorganisation of the, 997; Institute of Philosophy, Sir Herbert Samuel elected President of the, 64; Mineral Collectors and Dealers in the 17th, 18th, and 19th Centuries, A. Russell, 42; Museum: Lord Ilchester and Prof. J. Stanley Gardiner elected Trustees of the, 299; (Natural History): Acquisitions by the, 15, 181; the Diptera of Patagonia and South Chile, 407; Fiftieth Anniversary of the Opening of the, 578; Post-cards of British Trees, 671; Acquisitions by the, 755, 935; Optical Instruments, Exhibition of, 500; Patent System, Reform of the, 165; School of Archæology: in Athens, Report of the, 934; in Palestine, Work of the, Miss D. A. E. Garrod, 297; *Wood Preserving Association, Journal of the*, No. 1, 903
Broadcasting: Educational, Prof. Winifred Cullis, 877; Studios, Acoustical Problems of, N. Ashbridge, 844; the Song of the Nightingale, 217
Bromine in Organic Compounds, Estimation of, Prof. F. Schultz, 72
Bronze, The Metallurgy of, H. C. Dews, 627
Browne, Buckston, Farm for Surgical Research, Foundation-stone laid of the, 101
Brunton's, Guy, Expedition to Middle Egypt, Exhibition of the Finds of, 63
Budgerigars, The Breeding of, 60
Budget, Reductions under the, 487
Buenos Aires, Museum of Anthropology and Ethnography, Reorganisation of the, 903
Building Science Abstracts, 936
Bull, The Cult of the, in Scotland, A. D. Lacaille, 874
Bunsen Society in Vienna, The German, Prof. F. Paneth, translated by Dr. R. W. Lawson, 94
Burroughs, John, The Slabsides Book of, 834
Bushman, A Fossil, found in the Zuurberg Mountains, South Africa, F. W. FitzSimons, 611

Cable and Wireless Communications of the World, The, F. J. Brown. Second edition, 1057
Cables: High-voltage, Improved Method of constructing, M. Hochstadter, W. Vogel, and E. Bowden, 933; Steel-cored Aluminium, E. T. Painton, 1070
Caird, Sir James, Travelling Scholarships, award of the, 81
Calcium: Fluoride Method for the Determination of Fluoride, The, S. G. Clarke and W. N. Bradshaw, 1086; Triphosphate in a Soluble Form, A New Method for getting, P. Jolibois and G. Chaudron, 315
Calculus: Advanced, a Sequel to an Elementary Treatise on the Calculus, late Prof. G. A. Gibson, 851; Upwards and Downwards in the, 851
Calcutta School of Tropical Medicine, etc., Annual Report of the, 148
Calendar Reform, 38, 800; C. C. Wylie, 841
California Academy of Sciences, Report of Museum and Aquarium for 1930, 331
Calliphora ochracea Schiner (Diptera, Calliphoridæ), The Life-history of, Mary E. Fuller, 280
'Calorex' Glass, Tests with, Chance Bros. and Co., Ltd., 277
Cambridge: Philosophical Society, election of Officers, 834; University: Dr. C. E. Tilley elected Professor of Mineralogy and Petrology, 41; award of the Harkness Scholarship to Miss F. E. S. Caldwell and of Frank Smart prizes to P. W. Richards and P. Ullyett, 80; D. Keilin elected Quick Professor of Biology; W. J. Heasman appointed Senior Curator and G. J. Kerrich Junior Curator of the Museum of Zoology; E. E. Pochin elected Michael Foster Research Student in Physiology, 161; resignation of Dr. A. Harker; Dr. F. R. Winton appointed University Lecturer in Physiology; Dr. G. E. Holmes University Lecturer in Pharmacology, 420; Dr. T. W. Wormell reappointed Observer in Meteorological Physics; Dissertations approved for Degrees, 420; award of Research Exhibitions, 501; election of Prof. G. H. Hardy, L. C. Young, and H. S. M. Coxeter to Fellowships at Trinity College; A. H. Chapman appointed Official Secretary to the Engineering Department; Sir R. H. Biffen given the title of Professor Emeritus, 732; Gift from the Goldsmiths Company; J. W. A. F. Balfour-Browne elected a Frank Smart Student in Zoology; G. Bateson and R. O. Redman elected Fellows of St. John's College, 768; A. G. Brighton appointed Curator of the Sedgwick Museum of Geology; Prof. C. E. Tilley elected a Fellow of Emmanuel College; V. V. Narlikar elected an Isaac Newton Student and H. R. Hulme an additional Isaac Newton Student, 804; A. E. Watkins appointed University Lecturer in Cytology, Dr. E. J. Maskell University Lecturer in Plant Physiology, W. J. Dowson University Lecturer in Mycology, G. C. Grindlay University Demonstrator in Experimental Psychology, and E. H. B. Boulton reappointed University Lecturer in Forestry; H. R. Barnell appointed Frank Smart Student in Botany, 844; R. J. Pumphrey appointed University Demonstrator in Zoology; Grant to L. C. Beadle from the Balfour Fund, 880; Prof. A. Einstein appointed Rouse Ball Lecturer for 1931–32; Prof. D. Keilin elected a Fellow of Magdalene College; Dr. C. G. Lamb reappointed Reader in Electrical Engineering, and T. R. B. Saunders University Demonstrator in Engineering, 916; Dr. H. C. Darby appointed University Lecturer in Geography; recommended Recognition of certain Sub-departments, 1011; Dr. F. C. Phillips appointed University Lecturer in Petrology; recommendation of the General Board concerning Forestry in the University Curriculum, 1048

Canada: Goose, The, and its Races, H. A. Tavener, 874; North-West Territories of, Development of the Hudson Bay Region and the, Dr. Brysson Cunningham, 53; Royal Society of, Annual Meeting in Toronto, 275
Canal Rays, The Production of High-speed, without the Use of High Voltages, E. O. Lawrence and D. H. Sloan, 83
Cancer: A Method of Diagnosis of, Dr. Bendien, 438; and Scientific Research, Dr. Barbara Holmes, 136; Ministry of Health Memorandum on, 65; Research: 664; and the Scientific Method, Dr. Ellice McDonald, 407; Fund, Imperial, Report of the, 931
Canning Industry, English, Progress of the, 16
Cape Observatory, Report of the, 73
Capper Award, Dr. L. O. Howard recipient of the, 64
Caramel, The Analytical Characters of, regarded as a Colouring Matter for Food, P. Balavoine, 83
Carbon: Contacts, C. Turnbull; Prof. C. V. Boys, 968; Dioxide in Sea-water of Different Salt Contents, Apparent Dissociation Constants of, Dr. K. Buch, Dr. H. Wattenberg, and H. W. Harvey, 411; Disulphide: Change of Density of, with Temperature, Dr. J. Mazur, 673; Change of the Dielectric Constant of, with Temperature, Dr. J. Mazur, 761; Change of Dielectric Polarisation of, with Temperature, Prof. M. Wolfke and Dr. J. Mazur, 871; Flames, Spectrum of, Prof. A. Fowler and W. M. Vaidya, 192
Carbonaceous Minerals, The Classification of, Prof. H. Briggs, 72
Carboniferous Plants from Sinai, Prof. A. C. Seward, 1012
Carbonisation Test, Low Temperature, 841
Carbonyl Sulphide, Infra-red Absorption Spectrum of, C. R. Bailey and A. B. D. Cassie, 637
Carnegie: Foundation for the Advancement of Teaching, Annual Report, 880; United Kingdom Trust, The, 194
Carotene: and Vitamin A, Mlle. D. van Stolk, J. Guilbert, and H. Pénau, 467; Cause of the Transformation of, into Vitamin A, H. S. Olcott and D. C. McCann, 998; Pure, and Vitamin A, Mlle. D. van Stolk, J. Guilbert, H. Pénau, and H. Simonnet, 199; The Hæmatopoietic Power of, L. Binet and M. V. Strumza, 387; The Isolation of, from the Suprarenal Glands, O. Bailly and R. Netter, 1086
Carpenter, Edward, an Appreciation, Edited by G. Beith, 892
Catalytic Dehydrogenation, in the Gas Phase, of the Fatty Alcohols in the Presence of Pumice carrying Sulphuric and Phosphoric Acids, J. B. Senderens, 162
Cathode Phenomena in the Glow Discharge, Prof. A. Guntherschulze and F. Keller, 840
Caucasus to the Volga, Through the, Dr. F. Nansen. Translated by G. C. Wheeler, 319
Cavendish, Henry, 1731–1810, 608
Ce^{+++} Ion in Solution, Absorption Spectra of the, Prof. D. M. Bose and S. Datta, 270
Cellular Permeability: M. V. L. Homes, 1005; Action of Light upon, F. Chodat, 126
Cellulose: Lacquers, Dr. T. H. Durrans, 192; Sols, Anisotropy due to Flow in, J. M. Preston, 796
Central: America, Models of Temples in, Dr. G. C. Vaillant, 823; Asiatic Expeditions. The Permian of Mongolia: a Report on the Permian Fauna of the Jisu Honguer Limestone of Mongolia and its relations to the Permian of other parts of the World, Prof. A. W. Grabau. With a Chapter on the Relations of the Jisu Honguer Formation to the General Geology of Mongolia, by Dr. C. P. Berkey and F. K. Morris, 956; Australian Parrot, Strange acquirement of a, A. W. Mullen, 579
Cercariæ, Excretory System in, The Evolution of the, Lieut.-Col. R. B. S. Sewell, 459
Cerebro-Spinal Fever, Certain Aspects of the Control of, 332
Cerium, Pure, Preparation of, M. Billy and F. Trombe, 734
Ceylon, Flora of, A Hand-Book to the, H. Trimen. Part 6: Supplement, A. H. G. Alston, 891
Chamæleon, A Dwarf, with Two Litters, W. J. Pitt, 407
Changing World, The, 404
Charcoal: Activated, Hydrolytic Adsorption of, Prof. J. N. Mukherjee and S. P. Roychoudhury, 412; Activation by, W. D. Bancroft and S. F. Whearty, Jr., 280
Chastity: The Girdle of, a Medico-Historical Study, Dr. E. J. Dingwall, 628
Chelonia, Evolution in the, P. E. P. Deraniyagala, 273
Chemical: Analysis of Special Steels, Steel-making Alloys, their Ores, Graphites, and Bearing Metals, Rapid Methods for the, C. M. Johnson. Fourth edition, 288; Composition: an Account of the Methods by which Atomic Weights and Molecular Formulæ have been determined Dr. A. K. Goard, 958; Engineer, The, 622; Engineering, Elements of, Prof. W. L. Badger and Prof. W. L. McCabe, 622; Engineers, Institution of, H. W. Cremer appointed Honorary Secretary of the, 756; Forces, Nature of, 948; Industries, Safety Work in, 1; Industry: A History of the British, Dr. S. Miall, 45; Society of, Jubilee Celebrations of the: Dr. H. F. Gillbe, 157; Prof. G. T. Morgan, 226; Manipulation, Faraday's, Sir Robert Robertson and B. A. Ellis, 371
Chemie: anorganischen, Handbuch der, Herausgegeben von Prof. R. Abegg, Dr. F. Auerbach, und Prof. I. Koppel. Band 4, Abt. 3. Teil 2. A Lief. 1, 625; physikalischen, Lehrbuch der, Prof. K. Jellinek: Funf Bande. Band 3: Die Lehre von der Statik chemischer Reaktionen in verdunnten Mischungen (Losungen). Erste und zweite Auflage. Lief. 9, 852; Funf Bande. Lief. 10 (Band 4): Die Lehre von der Statik chemischer Reaktionen (Schlussteil) und die Lehre von der chemischen Kinetik. Erste und zweite Auflage, 958
Chemische: Bindung als elektrostatische Erscheinung, A. E. van Arkel und J. H. de Boer. Deutsche, von den Verfassern autorisierte Ausgabe von L. Klemm und W. Klemm, 816; Thermodynamik: Einführung in die Lehre von den chemischen Affinitaten und Gleichgewichten, Prof. H. Ulich, 52
Chemistry: Analytical, Recent Advances in, Vol 1: Organic Chemistry, Editor: Dr. C. Ainsworth Mitchell, 208; *and Industry*, Special Number, 101; Applied, in Technical Colleges, 678; for Matriculation, Dr. G. H. Bailey and H. W. Bausor. Third edition, 173; Inorganic: and Theoretical, A Comprehensive Treatise on, Dr. J. W. Mellor. Vol. 11, 957; Systematic, from the Standpoint of the Periodic Law, Prof. R. M. Caven and Dr. G. D. Lander. New edition, 209; in Technical Schools and Colleges in England and Wales, Instruction in, 678; Makers of, Dr. E. J. Holmyard, 321; of the Vitamins, Sir F. Gowland Hopkins and others, 842; Organic: An Introduction to, Prof. J. Read, 742; for Medical, Intermediate Science, and Pharmaceutical Students, Prof. A. K. Macbeth. Second edition, 657; Fundamentals of, Prof. H. F. Lewis, 957; Physical: A Textbook of Practical, Prof. K. Fajans and K. Wüst. Translated by B. Topley, 852; A Treatise on, a Cooperative Effort by a Group of Physical Chemists, Edited by Prof. Hugh S. Taylor. Second edition. In 2 volumes; Prof. C. K. Rideal, 429; and Colloidal, 852; Laboratory Technique in, 814; Practical, Prof. A. Findlay. Fifth edition, 959; Physiological, in the United States, The Development of, Prof. R. H. Chittenden, 90; Quantitative Pharmaceutical, containing Theory and Practice of Quantitative Analysis applied to Pharmacy, Prof. G. L. Jenkins and Prof. A. G. DuMez, 958; Synthetic Inorganic, a Course of Laboratory and Classroom Study for First Year College Students, Prof. A. A. Blanchard and Prof. J. W. Phelan. Fourth edition, 92; through the Ages, Prof. J. Read, 321
Cheshunt Experimental and Research Station, Report for 1931, 1071
Children, Young: Intellectual Growth in, Dr. Susan Isaacs. With an Appendix on Children's "Why" Questions, by Nathan Isaacs, 777; The Behaviour of, Jean Ayling, 777
Chimie, l'Union Internationale de, Dixième Conférence de, Liége, 14-20 septembre 1930. Rapports sur les hydrates de carbone (glucides), 656
China: National Medical Journal of, Aug.-Oct., 998; Nationalism and Science in, 469; Sir James Barrett, 1035

Chinese: Alchemist, A, Prof. J. Read, 509; Alchemy, Prof. J. R. Partington, 1074; Turkestan, Archæological and Geographical Exploration in, Reason for Abandonment of, Sir Aurel Stein, 144
Chlorides in Dairy Products and Biological Material, Determination of, W. L. Davies, 733
Chloro-tropane, Some Physiological Effects of, M. Polonovski and R. Hazard, 734
Choosing a Career, Methods of, F. M. Earle and others. Edited with a Preface by Dr. C. S. Myers, 393
Christianity, A Heathen's Thoughts on, E. Upasaka, 892
Chromosome Homologies in Wheat, Rye, and Aegilops, Prof. W. P. Thompson, 640
Chromosomes and Constitution, A. A. Moffett, 875
Chromosphere, Height of the, in 1930, G. Abetti, 1014
Chronic Deafness, Treatment of, by the Electro-phonoide Method of Zund-Burguet, Dr. G. C. Cathcart. Second edition, 563
Chrysanthemum and *Potentilla*, Chromosome Multiples in, N. Shimotomai, 72
Cinematograph, An Ultra-rapid, giving from 2000 to 3000 Images per second, E. Huguenard and A. Magnan, 163
Citrus Growing in Southern Rhodesia, 60
City and Guilds of London Institute, Report for 1930, 501
Civil: Engineering Design, A. A. Fordham, 962; Engineers, Institution of, awards of the, 834; Service, The Royal Commission on the, 201
Civilisation: Biology and, Dr. H. H. Dale, 897; The Epic and the Tragedies of, Sir Arnold Wilson, 902
Climatology, A. A. Miller, 514
Clinique-Manufacture Internationale, La, Dr. Rollier, 1072
Clockmakers' Company, Three-hundredth Anniversary of the, 1032
Clocks, Electric Pendulum, Prof. C. V. Boys, 651
Coagulation, Reversible, in Living Tissue (2), W. D. Bancroft and J. E. Rutzler, Jr., 280
Coal: and its Uses, R. Wigginton, 1024; Dust, Electrification of, S. C. Blacktin and H. Robinson, 498; Resources, National, The Physical and Chemical Survey of, 490
Cobalt Nitrosodithiocarbamates, L. Cambi and A. Gagnasso, 683
Cochita, New Mexico, Folk-Tales of the, Ruth Benedict, 970
Cockle, Growth of the, A. C. Stephen, 379
Cockroach, Temperature and Humidity Relations of the, D. L. Gunn, 186
Coco-nut Oil Industry, The, A. E. Williams, 755
Cod, The Greenland, 731
Cohesion, The Nature of, Prof. J. E. Lennard-Jones, 462, 763
Coil Ignition Systems for Motor Cars, E. A. Watson, 865
Cold: -blooded Animals, On the Metabolism of, Daphne L. Coulston, 316; Common, Cause of the, Dochez, Mills, and Kneeland, Jr., 438
Colloidal: (Explosive) Powders, Temperature of Deflagration of, A. Michel-Lévy and H. Muraour, 421; Gold, Magnetism of, V. I. Vaidhianathan and Balwant Singh, 302; Humic-mineral Complexes, Behaviour in an Electric Field of, C. Antoniani, 735; State, Diamagnetism and the, S. Ramachandra Rao, 153
Colloids: a Textbook, Prof. H. R. Kruyt. Translated by Prof. H. S. van Klooster. Second edition, 852; Coagulation of, by Electrolytes, Dr. B. N. Desai and P. M. Barve, 907
Colonial Office appointments, 112, 266, 670, 834, 998
Colorado: and Folsom Points, Dr. E. B. Renaud, 190; University, Theses presented to, 384
Colour Vision, Young's Theory of, Sir John H. Parsons, 123
Colours, Which, do all Colour-blind People fail to distinguish? Polack, 1050
Combustion, The Heat of, of Certain Organic Halogenic Compounds, I. Kaklukov and F. Perelmann, 127
Comet: New, 1931 *b*, 192; New Bright, 1931 *c*, 308; New, 841; Notes, Prof. G. van Biesbroeck, 416; Ryves, 1931 *c*, 381
Cometary: Observation by Bessel in 1832, A Possible, 121; Orbits and the Orbit of Pluto, Proximities of, G. Fayet, 163
Comets, 308, 876
Comets of Short Period, The Origin of, S. Vsessviatsky, 1045
Comma Butterfly in England, The, Dr. F. S. Dawe; N. D. Riley, 760; F. Tutin, 1041
Communications, Sir Oliver Lodge, 932
Conduits, Leçons sur les, Prof. C. Camichel, 209
Conejo, Explotación del, en la Argentina, 112
Congress, Washington, Report of the Librarian of, 219
Coniferous Plantation, The Artificial, and its Place in Forestry, E. P. Turner, 417
Constantan Wire, Lattice-distortion of Cold-drawn, W. A. Wood, 917
Contraceptive Advice, Bureau for, Statistical Report on Operations of the, Prof. R. Pearl, 180
Contraceptives, Chemical, Spermicidal Power of, J. R. Baker, 119
Co-operation between Scientific and Technical Societies and Institutions, Association for the Promotion of, Annual General Meeting, 996
Coopers Hill War Memorial Prize and Medal, award of the, to Dr. M. G. Say, 1072
Co-ordination, An Aspect of, Prof. J. Kenner, 1000
Copepod, A New Parasitic, Isokiti Harada, 37
Copper: Alloys, Oxidation of Some, J. S. Dunn, 594; and Copper-rich Alloys in the Form of Thin Strip, Physical Testing of, M. Cook and E. C. Larke, 554; Brittleness in, C. Blazey, 594; Ion, Activity Coefficient of the Bivalent, in Solutions of its Sulphate, Mlle. M. Quintin, 1050; -magnesium Alloys, The, W. R. D. Jones (4), 595; on Bismuth, Orientated Deposits of, Prof. Yosimiti Hori, 412; The Work-hardening Capacity and Elongation Properties of, H. O'Neill and J. W. Cuthbertson, 595
Coral Reefs and Atolls: being a Course of Lectures delivered at the Lowell Institute at Boston, February 1930, Prof. J. Stanley Gardiner, 206
Corals: and Zooxanthellæ, The Significance of the Relationship between, Dr. C. M. Yonge, 309; Symbiotic Algæ of, Capt. A. K. Totton; Dr. C. M. Yonge, 760
Corea, The Wolf of, Yoshio Abe, 71
Cornbrash, The Stratigraphical Distribution of the, J. A. Douglas and W. J. Arkell (2), 125
Cornish Geology, Handbook of, E. H. Davison. Second edition, 779
Corn-snake, A North American, and Moles, D. Butler, 579
Corona, Changes of the, in the Sunspot Cycle, Dr. W. J. S. Lockyer, 229

CORRESPONDENCE.

Abraxas, Effect of Certain Substances and of Heat on Cells of, Prof. J. B. Gatenby and Joyce C. Hill, 31
Acetylene, The Slow Combustion of, R. Spence, 153
Acromegaly: among the old Northmen, Prof. C. G. Seligman, 221; Prof. L. Hogben, 375; in the Far North, Dr. M. Perkins, 491; Prof. C. G. Seligman, 492
Active Nitrogen, An Oxidisable, Dr. E. J. B. Willey and S. G. Foord, 493
Adsorption, Activated, Prof. W. E. Garner, 583
Aerosols: Charged, and Ball Lightning, W. C. Reynolds, 584; Highly Charged, A Curious Phenomenon shown by, W. Cawood and H. S. Patterson, 150; Properties of, S. C. Blacktin, 968
African Prehistory, *Homo sapiens* and, E. J. Wayland, 1003
Agar-liquefying Bacteria, Distribution of, H. Nicol, 1041
Air Currents: Control of Humidity of, Dr. P. A. Buxton; Dr. W. H. J. Vernon and L. Whitby, 837; of Different Humidities, A Method of obtaining, Prof. J. B. Seth, 638
Aitken Condensation Nuclei, A. R. Hogg, 908
Alchemical Apparatus, Prof. J. R. Partington, 118
"All or None": a Question of Nomenclature, W. W. Waller, 70
Ammonium, Solid, Group Rotation in, and Calcium Nitrates, F. C. Kracek, S. B. Hendricks, and Dr. E. Posnjak, 410
Anchusa, Cytology of, and its relation to the Taxonomy of the Genus, S. G. Smith, 493
Anisotropy due to Flow in Cellulose Sols, J. M. Preston, 796
Anthocyanins, Constitution of, G. M. Robinson and Prof. R. Robinson, 413
Anthropology, Training of Colonial Probationers in, Col. T. C. Hodson, 458

AsH, The Band Spectrum of, G. E. Kimball and J. R. Bates, 969
Atmospheric Motion, Horizontal, The Energy of, Sir Napier Shaw, 226
Atoms and Molecules as Fitzgerald Oscillators, Sir C. V. Raman, 795
Aurora Polaris, Audibility of the, H. U. Sverdrup, 457
Australian Flora and Fauna, Preservation of the, Sir James W. Barrett, 1041
Azide Group, Structure of the, T. C. Sutton, 872
Azides, Structure of the: from their Electric Dipole Moments, L. E. Sutton, 639; Dr. E. Bergmann and W. Schütz, 1077
Band Spectra, Analysis of Complicated, with the Aid of Magnetic Rotation Spectra, Prof. R. W. Wood and G. H. Dieke, 545
Barium: Hydride, Bands in the Spectrum of, Dr. A. Schaafsma, 1042; Strontium and, New Isotopes of, Dr. F. W. Aston, 221
Benzene: and Toluene, Raman Spectra of, L. E. Howlett, 796; Melting Points of Nitrobenzene and of, Prof. I. Masson, 726
Bibliography of Science, Classification for, Dr. S. C. Bradford, 268
Black Stem Rust of Wheat, *Puccinia graminis tritici*, Effect of Light on Urediniospores of, W. A. R. Dillon Weston, 67
Blood of Aquatic Animals, The Composition of the, and its bearings upon the Possible Conditions of Origin of the Vertebrates, Prof. W. J. Dakin, 66
Bottle-Pipe Resonator, The, A. E. Bate, 270
Boys's Soap Solutions, Effect of Light on the Surface Tension of, Prof. L. D. Mahajan, 496; Dr. P. Lecomte du Nouy, 674
Carbon: Contacts, C. Turnbull; Prof. C. V. Boys, 968; Dioxide in Sea-Water of different Salt Contents, Apparent Dissociation Constants of, Dr. K. Buch, Dr. H. Wattenberg, and H. W. Harvey, 411; Disulphide: Change of Density of, with Temperature, Dr. J. Mazur, 673; Change of the Dielectric Constant of, with Temperature, Dr. J. Mazur, 761; Prof. M. Wolfke and Dr. J. Mazur, 871
Carbonyl Sulphide, Infra-Red Absorption Spectrum of, C. R. Bailey and A. B. D. Cassie, 637
Ce^{+++} Ion in Solution, Absorption Spectra of the, Prof. D. M. Bose and S. Datta, 270
Cellulose Sols, Anisotropy due to Flow in, J. M. Preston, 796
Charcoal, Activated, Hydrolytic Adsorption of, Prof. J. N. Mukherjee and S. P. Roychoudhury, 412
Chemical Industry, Society of, Jubilee Celebrations of the, Prof. G. T. Morgan, 226
Chinese Alchemy, Prof. J. R. Partington, 1074
Cockroach, Temperature and Humidity Relations of the, D. L. Gunn, 186
Colloidal State, Diamagnetism and the, S. Ramachandra Rao, 153
Colloids, Coagulation of, by Electrolytes, Dr. B. N. Desai and P. M. Barve, 907
Comma Butterfly in England, The, Dr. F. Sherwill Dawe; N. D. Riley, 760; F. Tutin, 1041
Co-ordination, An Aspect of, Prof. J. Kenner, 1000
Copper on Bismuth, Orientated Deposits of, Prof. Y. Hori, 412
Corals, Symbiotic Algæ of, Capt. A. K. Totton; Dr. C. M. Yonge, 760
Corpuscular Rays, Penetrating, coming from Inclined Directions, Measurements on the Absorption of the, Prof. B. Rossi, 408
Cosmic: and γ-Radiation, Biological Effects of, Prof. J. H. Orton and S. T. Burfield, 376; Evolution and Earthly Needs, Prof. H. E. Armstrong, 761; Rays: and Gamma Rays, Similarity between, Prof. R. A. Millikan and Dr. I. S. Bowen, 582; Magnetic Experiments on the, Prof. B. Rossi, 300; The Corpuscular Explanation of, Prof. F. Soddy, 408
Cotton Growing in Egypt, N. W. Barritt, 1001; F. P. Slater, 1002
Crystal Structure, Representation of, Prof. E. B. Bailey, 869
Crystals, Absorption Spectra of, at Low Temperatures as references in the Measurement of Stellar Velocities, S. Freed, 33
Cyanogen and the Cyanogen Halides, Ultra-Violet Absorption Spectra of, R. B. Mooney and H. G. Reid, 271
Daylight, Actinic Value of, Records of, G. J. Gibbs, 35
Deep Currents in the South Atlantic, Velocity of, G. E. R. Deacon, 267
Diamagnetism: and the Colloidal State, S. Ramachandra Rao, 153; of Liquid Mixtures, V. C. G. Trew and Prof. J. F. Spencer, 152
Doppler Effect in Light-Scattering, Sir C. V. Raman, 636
Dulcitol in a Red Seaweed, Occurrence of, Dr. P. Haas and Prof. T. G. Hill, 378
'Dust Devils', Rotation of, J. Durward, 412
Earthquakes, Deep-Focus, Rev. V. C. Stechschulte, 673
Eclipse Plumage in the Mallard, Violet K. Tallent, 672
Electric Circuit Breaker Research, E. B. Wedmore, A. M. Cassie, and W. B. Whitney, 675
Electrical: Conductivity of Quartz, Anomalous Variation of the, with Temperature at the Transformation Point, Prof. H. Saegusa and S. Shimizu, 835; Resistance and Energy of Magnetisation, A New Relation between, Prof. W. Gerlach and E. Englert, 151
Electricity Liberated during the Downgrade Reactions of Organic Compounds, Measurement of the, J. H. Wolfenden, 69
Electron: Diffraction Patterns, A Focusing Method for Producing, Dr. A. A. Lebedeff, 491; Exchange Phenomena in the Excited Atom, Prof. R. Whiddington and J. E. Roberts, 966
Electrons, Polarisation of a Beam of, by Scattering, E. G. Dymond, 149; N. F. Mott, 454
Embryology and the Theory of Polyhedra, Prof. D'Arcy W. Thompson, 31

Humidity in the Upper Air, Graphical Indication of, Dr. C. W. B. Normand, 583
Hydrocarbons : Slow Combustion of, Dr. R. Spence, 873 ; The Peroxidation of, during Combustion in Air, Dr. E. Mardles, 116
Hydrogen : Activated Adsorption of, by Zinc and Chromium Oxides, Prof. H. S. Taylor, 636 ; Atomic, occluded in Iron Nitride, Shun-Ichi Satoh, 457 ; Influence of, on Chemical Changes in Silver Vessels, Prof. M. W. Travers, L. E. Hockin, and T. J. P. Pearce, 66 ; Resonance Spectrum of, Dr. K. R. Rao and J. S. Badami, 585 ; Sulphide and Sulphur Dioxide, Reaction between, Prof. Basrur Sanjiva Rao and M. R. Aswathnarayana Rao, 413 ; The Critical Increment of the Adsorption of, on Amorphous Carbon at 400°-520° C., F. E. T. Kingman, 272
Hyperfine Structure, Isotopic Displacement in, J. H. Bartlett., Jr., 408
Immunity Reactions, The Study of Specific Combination in, J. R. Marrack and F. Campbell Smith, 1077
Indium and Thallium, Arc Spectra of, Fine Structure in the, Dr. A. L. Narayan, 675
Infra-Red Radiation from an Engine, An Investigation of, S. Steele, 185
Insect Metamorphosis, Effects of Inadequate Feeding on, C. Dover, 303 ; Dr. Hem Singh Pruthi, 869
Ions, Negative, Photoelectrons and, Dr. J. L. Hamshere, 871
Isotopes of Lead, Nuclear Moments of the : Relative Values of the $g(I)$ Factors of Pb(207) and Tl, Prof. J. C. McLennan, M. F. Crawford, and L. B. Leppard, 301
Jumping Negative Glow, The, W. A. Leyshon, 795
Keratin Molecule, Constitution of the, J. B. Speakman and Mercia C. Hirst, 1073
‘ Lapides palmati ’ mentioned in the “ Historia Naturalis ” of the Elder Pliny, The, Dr. K. C. Bailey, 672
Lavoisier, Priestley and, Sir Philip Hartog, 797
Lead, Isotopes of, Nuclear Moments of the : Relative Values of the $g(I)$ Factors of Pb(207) and Tl, Prof. J. C. McLennan, M. F. Crawford, and L. B. Leppard, 301
Lepidosiren, The Double Lateral Line of, J. T. Cunningham, 377
Light Quanta : Spin of, Sir C. V. Raman and S. Bhagavantam, 727 ; The Angular Momentum of, Sir C. V. Raman, 545 ; The penetration of, through Successive Layers of Tissue Paper, Dr. W. R. G. Atkins, 545 ; The Velocity of, Dr. V. S. Vrkljan, 269 ; Scattering, Doppler Effect in, Sir C. V. Raman, 636 ; in Liquids, S. Venkateswaran, 870
Lightning : Ball, Charged Aerosols and, W. C. Reynolds, 584 ; Branching of, Dr. B. F. H. Schonland and Dr. T. E. Allibone, 794 ; Major J. L. P. Macnair, 969 ; Discharge, Duration and Magnitude of a, R. S. J. Spilsbury, 872 ; Unusual, H. E. Beckett and A. F. Dufton, 189 ; Capt. C. J. P. Cave, 378
Liquid Mixtures : Diamagnetism of, V. C. G. Trew and Prof. J. F. Spencer, 152 ; Dr. H. Buchner, 301 ; Prof. E. van Aubel, 455 ; S. Ramachandra Rao and G. Sivaramakrishnan, 872 ; The Viscosity of, Prof. G. W. Stewart, 727 ; Prof. E. N. da C. Andrade, 835
Lithium : Constitution of, Dr. F. W. Aston, 149 ; Hydride, Isotope Effect in the Band Spectrum of, Prof. Gisaburo Nakamura, 759 ; Metallic, The Excitation Potentials of, Dr. H. W. B. Skinner, 114
Lithothamnion in the South Indian Cretaceous, Occurrence of, Prof. L. Rama Rao, 225, 873
London Skull, The, C. N. Bromehead, 118
Loudspeaker Frequency Response Curves in terms of Loudness, Subjective Interpretation of, D. A. Oliver, 268
Magnetic : Birefringence, A New Type of, Sir C. V. Raman and S. W. Chinchalkar, 758 ; Experiments on the Cosmic Rays, Prof. B. Rossi, 300
Magnetisation, Energy of, Electrical Resistance and, A new relation between, Prof. W. Gerlach and E. Englert, 151
Magneto-Electric Saturation Effect, The, Dr. O. E. Frivold and S. Koch, 675
Mallard, Eclipse Plumage in the, Violet K. Tallent, 672
Matter : Life : Mind, A. Eagle ; W. W. L., 906 ; Dr. W. D. Lighthall, 907 ; Dr. M. Copisarow, 1042
Meatal Notch, The External, as a Primitive Character, Prof. F. Wood Jones, 458
Melanism in Moths, Inheritance of, A. W. McKenny Hughes, 496
Mercury : Band, Spectrum in the, Fluorescence, Lord Rayleigh, 724 ; Cadmium, and Zinc, High Frequency Discharge of, The Forbidden Lines in the, J. Okubo and E. Matuyama, 224 ; Line Spectrum in Fluorescence, Lord Rayleigh, 905 ; Measurements of the Height of a Large Drop of, R. S. Burdon, 456
Methane and Ethane, The Slow Combustion of, Prof. W. A. Bone, 188 ; Dr. E. Mardles, 304
Molecules, Atoms and, as Fitzgerald Oscillators, Sir C. V. Raman, 795
Molybdenum Trioxide : Crystal Structure of, a Correction, Nora Wooster, 35
Monohydric Phenols, Application of the Simonis Reaction to, A. Robertson, 908
Mosquito Larvæ, Ultra-Violet Rays and, Dr. M. E. MacGregor, 68
Mousterian (Levalloisian) Implements, Derived early, in the Melt-water Gravels of the Coombe Rock Glaciation, J. P. T. Burchell, 909
Multiple Ionisation and Secondary X-Ray Absorption Edges, A. Sandstrom, 759
National Needs, L. A. Fenn, 909
Nemertean, A New and Peculiar Marine, from the Australian Coast, Prof. W. J. Dakin and Mahalah G. C. Fordham, 796
Neon-Helium Bands, Dr. M. J. Druyvesteyn, 1076
Nitrobenzene : Change of Dielectric Polarisation of, with Temperature, Prof. M. Wolfke and Dr. J. Mazur, 584 ; Melting Points of, and of Benzene, Prof. I. Masson, 726
Œnothera, Origin of Chromosome Linkage in, Prof. R. A. Gates and D. G. Catcheside, 637
Œstrus-producing Hormones, Dr. G. F. Marrian and A. Butenandt, 305
Ogilvie, Sir Francis, The late, J. Cameron Smail, 118
Oldoway : Bone Beds : Tanganyika Territory, Age of the, Dr. L. S. B. Leakey, A. T. Hopwood, and Prof. H. Reck, 724 ; New Yields from the, Dr. L. S. B. Leakey, A. T. Hopwood, and Prof. H. Reck, 1075 ; Human Skeleton, The, J. Reid Moir, 797
Opacity Coefficient, The Relativistic, R. C. Majundar and D. S. Kothari, 909
Oxlip, Wild, Segregation of Floral Characters in the, Prof. F. E. Weiss, 305
Oxygen and Everest, N. E. Odell, 1037
Ozone, Photosensitised Decomposition of, by Bromine, J. W. T. Spinks, 548
Phosphorus, Green Flame of, Band Spectrum of the, Dr. E. B. Ludlam, 271
Photoelectrons and Negative Ions, Prof. E. M. Wellish, 547 ; Dr. J. L. Hamshere, 871
Photon : Evidence of the Spin of the, from Light-Scattering, Sir C. V. Raman and S. Bhagavantam, 114 ; Dr. G. Placzek, 410 ; The Spin of the, Prof. W. N. Saha and Y. Bhargava, 870 ;
Plants, Mortality among, and its bearing on Natural Selection, R. Weatherall, 33

Polarisation of Downcoming Wireless Waves in the Southern Hemisphere, Prof. E. V. Appleton, 1037
Polarity and Vapour Pressure, Dr. A. R. Martin, 456
Polyhedra, Embryology and the Theory of, Prof. D'Arcy W. Thompson, 31
Potassium, β-Radiation of, A Hard Component of the, D. Bocciarelli, 374
Potatoes, Respiration of Healthy and Leaf Roll, Dr. T. Whitehead, 967
Pottery with Flint Implements of Upper Palæolithic Facies from Swanscombe, Kent, J. P. T. Burchell, 548
Precipitation, Periodic, in the Absence of Colloids, Prof. J. W. McBain, 1042
Prickly-Pear, Control of, by the Cochineal Insect, C. T. Jacob, 117; W. B. Alexander, 226; T. V. Ramakrishna Ayyar, 837
Priestley and Lavoisier, Sir Philip Hartog, 797
Prophylaxis, Experiments in, Sir Flinders Petrie, 35
Proteins in their Native State, Molecular Weights of the, Prof. The Svedberg, 999
Puccinia graminis tritici, Effect of Light on Urediniospores of Black Stem Rust of Wheat, W. A. R. Dillon Weston, 67
Quantised Magnetic Poles, Isolated, Prof. O. W. Richardson, 582
Quantum-Mechanical Models of a Nucleus, R. H. Fowler, 453
Quartz, Anomalous Variation of the Electrical Conductivity of, with Temperature at the Transformation Point, Prof. H. Saegusa and S. Shimizu, 835
Radioactivity and Earth Movements, Prof. A. Holmes, 496
Rainfall as Carbohydrates, Conservation of, Prof. W. A. Osborne, 378
Raman: Band of Water, Structure of the, S. Rafałowski; Dr. G. Bolla, 546; Lines due to Co-ordination Bond, Prof. D. M. Bose and S. Datta, 725; in Liquids, Fine Structure of, Dr. A. Langseth, 225; Scattering in Gases, Intensity of, S. Bhagavantam, 272; Scattering, Polarisation of, by Hydrogen Gas, S. Bhagavantam, 70; Spectra: Effect of Pressure on, S. Bhagavantam, 188; of Benzene and Toluene, L. E. Howlett, 796; of Crystals, Lines of Large Frequency Shift in the, Prof. R. Tomaschek, 495; of Liquid Mixtures, P. Krishnamurti, 639
Rare Gas Spectra, Intensity Anomalies in, E. Rasmussen and H. Swenson, 188
Relativistic Opacity Coefficient, The, R. C. Majumdar and D. S. Kothari, 909
Resonator, The Bottle-Pipe, A. E. Bate, 270
Rhenium, Magnetic Resolution and Nuclear Moment of, Prof. P. Zeeman, J. H. Gisolf, and T. L. de Bruin, 637
Rocks, Lead Content of, Prof. G. Hevesy and Dr. R. Hobbie, 1038; Prof. A. Holmes, 1039
Rotatory Magnetic Polarisation, Prof. E. van Aubel, 1004
Rubidium Spectrum, Hyperfine Structure in the, D. A. Jackson, 34
Salt Hydrate, Dissociation of a, Function of Water Vapour in the, B. Topley and M. L. Smith, 302
Salts, Dehydration of, Dr. M. Copisarow, 838
Science, Bibliography of, Classification for, Dr. S. C. Bradford, 268
Scientific Abstracting Services, Organisation of, A. A. Eldridge, 1004
Seedlings in some Grasses, Latency of, H. G. Chippindale, 1075
Serum Albumin, Denaturation of, Temperature Stability and, Prof. K. O. Pedersen, 150
Ship-Waves, Rhythmic Breaking of, Prof. Kerr Grant, 838
Short-Wave Reception and Ultra-Radiation, Dr. W. M. H. Schulze, 837
Silica Vessels, Chemical Changes in, Influence of Hydrogen on, Prof. M. W. Travers, L. E. Hockin, and T. J. P. Pearce, 66
Silver, Bivalent, Paramagnetism of, Prof. G. T. Morgan and Dr. S. Sugden, 31
Simonis Reaction, Application of the, to Monohydric Phenols, A. Robertson, 908
Snakes, Insectivorous, Prof. F. J. Meggitt, 413
Sound in Tubes: Velocity of, Ultrasonic Method, G. S. Field, 117
Space Lattice, A Two-Dimensional, Dr. R. C. Menzies 907; W. Baker, 1078
Special Lines of Light scattered by Liquids, The Fine Structure of, S. Rafałowski, 495
Spectrum Se III, The Structure of the, J. S. Badami and Dr. K. R. Rao, 496
Stars: White Dwarf, Constitution of the, Seitarô Suzuki, 838; White Dwarf, The Internal Temperature of, Prof. E. A. Milne, 999
Stellar Velocities, Measurement of, Absorption Spectra of Crystals at Low Temperatures as References in the, S. Freed, 33
Stratified Clouds, Electrical Conditions in, Dr. M. Grabham, 969
Strontium and Barium, New Isotopes of, Dr. F. W. Aston, 221
Superconductivity: a Polarisation Phenomenon, Prof. J. C. McLennan, 373; at High Frequencies, Prof. J. C. McLennan, A. C. Burton, A. Pitt, and J. O. Wilhelm, 1004
Surface Films, A Method of Studying, Prof. E. Gorter and W. A. Seeder, 413
Temperature Stability and Denaturation of Serum Albumin, Prof. K. O. Pedersen, 150
Thallium: II, Hyperfine Structure of, Dr. J. B. Green and J. Wulff; Dr. J. Schuler and J. E. Keyston, 409; and Uranium, Constitution of, Dr. F. W. Aston, 725; Indium and, Arc Spectra of, Fine Structure in the, Dr. A. L. Narayan, 675
Theophylline Arabinoside, The Pyranoid Structure of Glucuronic Acid and of, J. Pryde and R. T. Williams, 187
Thrips tabaci as a Vector of Plant Virus Disease, G. Samuel and J. G. Bald, 494
Ticks, The Spermatogenesis of, Prof. E. Warren, 454
Tigroid, Chemical Nature of the, Prof. A. Szent-Györgyi, 761
Titanium in the Tetrachloride, Valency and Diamagnetism of, Dr. V. I. Vaidhianathan, 189
Toluene, Benzene and, Raman Spectra of, L. E. Howlett, 796
Tomlinson, the late Mr. Herbert, J. J. Abraham, 153
Trifluorides of Aluminium, Iron, Cobalt, Rhodium, and Palladium, Structure of the, J. A. A. Katelaar, 303
Turbulence in a River, Dr. H. Jeffreys, 1078
Ultra-: Radiation, Short Wave Reception and, Dr. W. M. H. Schulze, 837; Violet: Light of the Sky, An Apparatus for Recording the, Dr. P. W. Cunliffe, 35; Radiation, Measurement of, A. F. Dufton and H. E. Beckett, 223; Rays and Mosquito Larvæ, Dr. M. E. MacGregor, 68
Uranium, Thallium and, Constitution of, Dr. F. W. Aston, 725
Uric Acid, Excretion of, Dr. V. B. Wigglesworth, 116; Dr. J. Needham, 152
Uteroverdin, Dr. R. Lemberg, Prof. J. Barcroft, and Dr. D. Keilin, 967
Virus Disease of the Tobacco Plant, A New, Dr. H. H. Storey, 187
Viruses, Nature of, Prof. A. E. Boycott, 727
Viscosity of Liquids, The, Prof. G. W. Stewart, 727; Prof. E. N. da C. Andrade, 835
Vitamin: A and the Antimony Chloride Reaction, A. Emmerie, M. v. Eekelen, and Prof. L. K. Wolff, 495; D, Crystalline, F. A. Askew, Miss H. M. Bruce, Dr. R. K. Callow, St. J. L. Philpot, and T. A. Webster, 758
Water Vapour in the Dissociation of a Salt Hydrate, Function of, B. Topley and M. L. Smith, 302
Weiss Units, The Theoretical Magneton Numbers in, Dr. C. J. Gorter, 68
White Dwarf Stars, Constitution of the, Seitarô Suzuki, 838
Wires drawn through Rotating Dies, H. Greenwood and Prof. F. C. Thompson, 152
Wood Fibres, The Tertiary Wall of, S. H. Clarke, 1078
World List of Scientific Periodicals, The, Sir Peter Chalmers Mitchell, 70
X-Ray: Diffraction Intensities, Anomalous, W. A. Wood, 272; Fibre Photography, S. Zeidenfeld, 70
X-Rays, Part-Absorption in, Dr. B. B. Ray and B. B. Datta, 224
Yard, Determination of the, in terms of the Wave-length of Light, J. E. Sears, Jr.; Dr. A. E. H. Tutton, 965
Yeast, Oxidation Reduction Potential of Complex Iron Compounds in, T. B. Coolidge, 223
Zeeman Effect of a Forbidden Line, E. Segrè and Dr. C. J. Bakker, 1076

Corrosion Problems, Thin Films in Relation to, U. R. Evans, 489
Cosmic: and γ-Radiation, Biological Effects of, Prof. J. H. Orton and S. T. Burfield, 376; Evolution and Earthly Needs, Prof. H. E. Armstrong, 761; Problems: an Essay on Speculative Philosophy, Prof. J. S. Mackenzie, 628; Radiation, Fluctuations in, G. Hoffmann, 120; Rays: and Gamma Rays, Similarity between, Prof. R. A. Millikan and Dr. I. S. Bowen, 582; Magnetic Experiments on the, Prof. B. Rossi, 300; The Corpuscular Explanation of, Prof. F. Soddy, 408; The Nature of, Prof. C. Størmer, 83
Cosmical Constant, The, and the Wave Equation, Sir Arthur Eddington, 763
Cotton: Cross-Pollination in, Dr. M. A. Fikry, 1080; Growing in Egypt, Dr. W. L. Balls, and others; F. P. Slater, 766; N. W. Barritt, 1001; F. P. Slater, 1002
Craven Area, Jointing and Tectonics of the, L. R. Wager, 460
Crayfish, Lateral Giant-fibres in the, Histological Polarisation of, S. G. Warner, 164
Creative Science and Industry, 317
Cresols, A Method of separating the, and the Properties of Pure *m*-Cresol, G. Darzens, 315
Crime as Destiny: a Study of Criminal Twins, Prof. J. Lange. Translated by Charlotte Haldane, 630
Crimea, Rodents from the Quaternary Deposits in the, A. A. Birula, 127
Criminal Statistics, 1929, 61
Crompton Medal of the Institution of Automobile Engineers, Award of the, to Dr. S. J. Davies and E. Giffen, 635
Cross, Dorothy Temple, Fellowships, Award of, 220
Cruciferous Flower, Structural Features of the, Dr. Agnes Arber, 1043
Crude Oil, Relation between the Yield of, and the Composition of Retortable Carbonaceous Minerals, H. Briggs, 42
Crustacea, Musculature of, Dr. R. J. Daniel, 970
Crust-Movements after the Tango Earthquake of 1927, Prof. C. Tsuboi, 380
Cryptotoxins, New Researches on the, H. Vincent, 918
Crystal: Palace Show, Exhibits at the, 995; Structure Representation of, Prof. E. B. Bailey, 869
Crystallisation Centre, The Nature of a, A. Glazunov, 128
Crystallography, The New, Prof. W. L. Bragg, 511
Crystals: of Brookite Tabular Parallel to the Basal Plane, F. C. Phillips, 977; Structure of XO_3 Groups in, W. H. Zachariasen, 274
Cuckoo, Feeding of a Yearling, 296
Culture Media, A Compilation of, for the Cultivation of Micro-organisms, Prof. M. Levine and H. W. Schoenlein, 244
Cuprous Oxide: Cells, Variation in the Spectrum of the Sensibility of, P. Auger and C. Lapicque, 646; Photoelectric Cells, Sensibility of, of the Type with Copper Grid, L. Dubar, 918
Current Economic Theory in Relation to the Five-Year Plan, M. Dobb, 790
Currents, Deep, in the South Atlantic, Velocity of, G. E. R. Deacon, 267
Cyanidin Chloride, Constitution of, Dr. M. Nierenstein, 587
Cyanogen: and the Cyanogen Halides, Ultra-Violet Absorption Spectra of, R. B. Mooney and H. G. Reid, 271; The Absorption Spectra of, and the Cyanogen Halides, R. B. Mooney and H. G. Reid, 882
1, 2-Cyclohexanedione or Dihydro-pyrocatechol, E. Urion, 315

Dabtara abyssin, Le livre de recettes d'un, M. Griaule, 204
Dairy Research, Sir William Dampier, 1071
Daylight, Actinic Value of, Records of, G. G. Gibbs, 35
Dean, Bashford, Memorial Volume, Archaic Fishes, Edited by Dr. E. W. Gudger, 182
Death and Development, Prof. E. W. MacBride, 382
Debye-Huckel Equation, Activity Coefficients and the, 499
Decimal Classification, Universal, 680
Delphinium, Mutable Genes in, Demerec, 676
Demography, History of, 940
Deserts and the Birth of Civilisations, A. J. McInerny, 475
Deutschlands, Stratigraphie, Handbuch der vergleichenden, Alluvium, Schriftleitung, late Prof. J. Stoller. Unter Mitwirkung von K. von Bulow und W. Dienemann, 1025
Diamagnetism: and the Colloidal State, S. Ramachandra Rao, 153; of Liquid Mixtures, S. Ramachandra Rao and G. Sivaramakrishnan, 872
Diatomic Gases, Scattering by, E. O. Wollan, 1014
Diatoms Growing on Stones on the Black Sea Littoral near Sebastopol, N. F. Alexeenko, 422
Dielectric Constant, The, and Chemical Constitution, A. Chrétien, 163
Diencephalon, A possible 'Parasympathetic Centre' in the, H. Cushing, 422
Diet: and Disease, 326; The 'Vital' Factor in, Dr. C. Watson, 154
Diffusion for the Infinite Plane Sheet, A. T. McKay, 733
Dinaphthopyrone, A New Method of Synthesis of, K. Dziewonski and S. Pizoń, 279
Dinoflagellates, Japanese, Prof. C. A. Kofoid, 154
Diopside and Tremolite from Monte Spinosa in the Campigliese, F. Rodolico, 1014
Diptera of Patagonia and South Chile, Part 6, fasc. 2, 112
Disasters at the Moon's Third Quarter, A. Rosewood, 997
Discharge: Tubes and their Technical Applications, N. L. Harris and H. G. Jenkins, 330; without Electrodes, The Theory of the, F. Esclangon, 82
Disease, Diet and, 326
Dissociable Organic Oxides, Researches on the, C. Dufraisse and M. Badoche, 422
Dissolved Substance, Distribution of a, between the Crystalline and the Fluid Phase, V. Chlopin and A. Ratner, 387
Diving Devices, Modern, Capt. G. C. C. Damant, 324
Domestic Animals, The Sensibility of, to the Virus of Exanthematic Fever, G. Blanc and J. Caminopétros, 503
Dominance, Evolution of, Dr. R. A. Fisher, 1079
Donohoe Comet Medal, award of the, to M. Nagata, 868
Doppler Effect in Light-Scattering, Sir C. V. Raman, 636
Drumm Storage Battery, Use of, in Ireland, 994
Dry: Cleaner, Practical, Scourer and Garment Dyer. Edited by W. T. Brannt and J. B. Gray. Sixth edition, 1060; Liquids, Distillation of, J. W. Smith, 971
Drying, Mechanism of, Dr. G. Bozza, 380
Dulcitol in a Red Seaweed, Occurrence of, Dr. P. Haas and Prof. T. G. Hill, 378
Duralumin, Influence of Variations in Heat-treatment and Ageing on, A. von Zeerleder, 554
Durham University, Philosophical Society of, election of officers, 723
'Dust Devils', Rotation of, J. Durward, 412
Dyestuff Industry: Advances in the, Prof. F. Mayer, 792; The, Prof. H. E. Armstrong, 542
Dynamic Universe, The, Prof. J. Mackaye, 288

β-ethylnaphthaline and its Hydrogenation Products, G. Lévy, 163
Ear, The Cupula of the, R. E. Bowen, 846
Early Man in North-East Yorkshire, F. Elgee, 776
Earth: Interior of the, Composition of the, A. A. Bless, 280; Physics of the: Volcanology; The Figure of the Earth; Meteorology; The Age of the Earth, Dr. H. Jeffreys, 984; Movements, Radioaction, and, Prof. A. Holmes, 496
Earthquake: in Western China, 407; Recorded at Kew, 332; The Idu (Japan) of Nov. 26, 1930, Dr. C. Davison, 552; The North Sea, Rev. J. P. Rowland, 15
Earthquakes: and Mineral Springs, B. M. Radoslavoff, 677; Deep-Focus, F. J. Scrase, 228; Rev. V. C. Stechschulte, 673; Luminous Phenomena accompanying, K. Musya, 155; Recent, 299
Earths: and Alkaline Earths, Preparation of the Cyanamides of the, Mlle. Germaine Bernheim, 315
Earth's Crust, Properties of the, 549

Earwig, Function of the Forceps of the Common, M. H. Lapidge and Dr. van der Sleen, 756; F. G. Carruthers, 440
Echinoderm Larvæ, Prof. T. Mortensen; Dr. F. A. Bather, 417
Echinostomes from Rats, A. Tubangui, 227
Eclipse Observations and the Einstein Shift, Prof. E. Freundlich, 1045
Ecological Viewpoint, The, Prof. J. W. Bews, 245
Edinburgh University: conferment of Honorary and other Doctorates, 80; Dr. C. McNeil appointed Edward Clark Professor of Child Life and Health in, 197; E. G. Dymond appointed Lecturer in Natural Philosophy; Dr. E. L. Ince, Lecturer in Mathematics; Dr. R. A. R. Gresson, Lecturer in Zoology (Cytology); Dr. P. Gray, Lecturer in Zoology (Vertebrate Embryology); and Lt.-Col. S. H. Cowan, Lecturer in Forest Engineering, 880
Educational Broadcasting, Prof. Winifred Cullis, 877
Eels and Conger Eels of the North Atlantic, Prof. J. Schmidt, 602
Egg, Development of the, Dr. G. L. Streeter, 1005
Egypt: Ancient, Hippopotamus Figures from, W. M. Crompton, 273; and the Sudan, Hand-spinning in, Mrs. Grace M. Crowfoot, 71; Cotton Growing in, N. W. Barritt, 1001; F. P. Slater, 1002; Palæolithic Man in, 287
Egyptian: Figurine, An Archaic, G. Loukianoff, 640; Sealings, Ancient, Dr. G. A. Reisner, 1079
Einnamic Aldehyde, A New Method of Synthesis of, and its Homologues substituted in the Nucleus, L. Bert and R. Annequin, 125
Einstein: Shift, Eclipse Observations and the, Prof. E. Freundlich, 1045; Universe, Static, On Thermodynamic Equilibrium in a, R. C. Tolman, 164
Eiszeitalter: Das; Grundlinien einer Geologie des Diluviums, Dr. P. Woldstedt, 394
Elastic Equilibrium, The Intrinsic Equations of, G. Andruetto, 734
Electric: and Magnetic Units, The Convention of Equidimensional, A. E. Kennelly, 164; Circuit Breaker Research, E. B. Wedmore, A. M. Cassie, and W. B. Whitney, 675; Clocks, F. Hope-Jones, 651; Field at the Summit of the Puy de Dôme, The, E. Mathias and G. Grenet, 806; Light and Power: Supply Companies, The Interconnexion of, Prof. K. Field, 297; Companies, Unification of, Capt. J. M. Donaldson, 755; Stations: Two Historic, Dr. G. A. Orrok; Col. R. E. B. Crompton, 140; Value of Linking Up, N. E. Funk, 669; Propulsion of Liners, A. D. Constable, 16; Traction Experiment in Ireland, An, 994
Electrical: Engineers, Institution of: award of Scholarships by the, 278; election of Officers of the, 147; Oscillator of Low Frequency Stabilised by a Tuning Fork, An, G. Marboux, 42; Resistance and Energy of Magnetisation, A New Relation between, Prof. W. Gerlach and E. Englert, 151; Supply, Application of, for the Provision of Labour-saving Devices, 62; System, A Self-maintained, utilising a Neon Tube, B. Decaux and P. Le Corbeiller, 978
Electricity: and Magnetism: A Connexion between, Dr. P. A. M. Dirac, 586; an Advanced Text-book for Colleges, Prof. C. A. Culver, 629; Physical Principles of, Prof. R. W. Pohl. Translated by Winifred M. Deans, 134; and the Soil, 252; for Everybody: Handbook for 1931, R. B. Matthews, 960; in the Rumanian Oilfields, Use of, H. E. Dralle, 633; Liberated, Measurement of the, during the Downgrade Reactions of Organic Compounds, J. H. Wolfenden, 69; Magnetism and, School Certificate, Dr. H. Toms, 431; Supply, Standardisation of, 16; The Mechanical Aspects of, Ll. B. Atkinson, 865
Electrification of Railways of Great Britain, The, 179
Electrochemistry, A Laboratory Manual of, Prof. E. Muller. Translated by Dr. H. J. T. Ellingham, 743
Electrodynamic Relations in Electromagnetic Machinery, The Fundamental Features of, E. Semičev, 126
Electrodynamics: Certain Fundamental Theorems of, and of the Statics of Elastic Solids (2), D. Bonvicini, 806; Gauss's Investigations on, Prof. C. Schaefer, 339
Electrokinetic Potentials, Studies on, H. B. Bull and R. A. Gortner (9), 423
Electrokinetics and the Interpretation of Surface Conductivity, McBain and Du Bois, 677
Electrolysis, Quantum Theory of, Dr. R. W. Gurney, 1044
Electrolytes in Solution, Behaviour of, Sir Harold Hartley, and others, 680
Electromagnetic Waves: Propagation of, Prof. H. Nagaoka, 120; Reflection of very Short, R. Guyot, 503
Electromagnetism, Dynamical Aspects of, Prof. V. K. F. Bjerknes, 369
Electron: Diffraction, Prof. D. R. Hartree, 47; Diffraction Patterns, A Focusing Method for Producing, Dr. A. A. Lebedeff, 491; Exchange Phenomena in the Excited Atom, Prof. R. Whiddington and J. E. Roberts, 966; -Inertia Effect, A New, Prof. Barnett, 549; Theory, A Generation of, O. U. Vonwiller, 200
Electronic Impacts in Air, The Ionising Efficiency of, J. Thomson, 81
Electrons: Diffraction of, F. L. Arnot and E. C. Bullard; H. S. W. Massey, 799; Polarisation of a Beam of, by Scattering, E. G. Dymond, 149; N. F. Mott, 454
Elektroneninterferenzen, Herausgegeben von Prof. P. Debye, 396
Elektrophorese, Elektroosmose, Elektrodialyse in Flussigkeiten, Dr. P. H. Prausnitz und Dr. J. Reitstötter, 988
Element: of Atomic Number 87, Reported Identification of the, by Dr. J. Papish, 696; 61, Investigation on, by means of the X-Rays, S. Takvorian, 82; No. 87, The Discovery of, Papish and Wainer, 789
Elks (*Alces* Gray) of the Old World, K. K. Flerov, 503
Empire: Cotton Growing Corporation, Quarterly Report of the Executive Committee, 754; Marketing Board, Report of the, 1930–31, 251; Survey Officers, Conference of, 276; *Survey Review*, pt. 1, 266; Travel for British Students, 196
Employment in Great Britain, Fluctuations in, Dr. F. C. Benham, 753
Encke's Comet, 38; H. E. Wood, 156
Endothermic Compounds, The Maximum Concentration of, at High Temperatures, E. Briner and B. Susz, 83
Engineering: Apprentices, Selection of, 463; Societies Monographs, Projected, 183
Entomological Society of London, The Transactions of the, vol. 79, part 1, 689
Entomology: Agricultural, A Textbook of, Dr. Kenneth M. Smith; Dr. A. E. Cameron, 943; A History of, Prof. E. O. Essig, 655; Applied, 655
Environment and Plant Development. Being "Klima und Boden in ihrer Wirkung auf das Pflanzenleben", Prof. H. Lundegårdh. Translated and edited by E. Ashby, 135
Enzyme-Substrate Reactions, Contraction Constants of, M. Sreenivasaya and H. B. Sreerangachar, 585
Ephedrine and related Substances, K. K. Chen und C. F. Schmidt, 629
Epidemiological Essays, Dr. F. G. Crookshank, 323
Equality, R. H. Tawney, 964
Eros, The recent Opposition of, Prof. J. Hartmann and M. Dartayet, 550
Erzmikroskopische Bestimmungstafeln: Anhang zum Lehrbuch der Erzmikroskopie, Prof. H. Schneiderhohn und Prof. P. Ramdohr, 889
Erzmikroskopie, Lehrbuch der, Prof. H. Schneiderhöhn und Prof. P. Ramdohr, Band 2, 889
Esperanto in Scientific Literature, R. M. Morris-Owen, 969
Ethane, Methane and, The Slow Combustion of, Dr. E. Mardles, 304; Prof. W. A. Bone, 188
Ethnos: or the Problem of Race considered from a New Point of View, Sir Arthur Keith, 624
Ethyl: Alcohol, Synthesis of, Prof. G. T. Morgan and R. Taylor, 38; Radical, Isolation of the, Prof. Paneth and Lautsch, 1007; Thio-aceto-acetate, Synthesis of, Sir P. C. Rây, 189
Ethylene, Oxidation of, Lenher, 912
Ethylmagnesium Bromide, Action of, on *N*-diethylmonochloracetamide, Sou Phou Ti, 199
Eugenics, Positive, in Practice, A. Dachert, 147
Eurymelinæ (Cicadelloidea, Homoptera), Biology and Morphology of the, J. W. Evans, 387
Eurytemora thompsoni, A. Willey: a New European Record, A. G. Lowndes, 967
Everest, Oxygen and, N. E. Odell, 1037; Dr. R. Greene, 893

Evolution: revealed by Palæontology, The Principles of, Prof. H. F. Osborn, 894; Some Examples of, H. Douvillé, 918; The Evidence of Palæontology with regard to, Prof. A. E. Trueman, 990
Evolutionist, A Complete, 429
Ewing's Model of the Magnetic Atom, The Specific Heat of Ferromagnetics and, Dr. J. R. Ashworth, 1003
Exanthematic Fever in Man caused by *Rhipicephalus sanguineus*, J. Troisier and R. Cattan, 422
Expansion, The Phenomena of, Presented by certain Electrolytic Deposits of Metals, C. Marie and N. Thon, 421
Experimentalphysik, Handbuch der. Herausgegeben von W. Wien und F. Harms. Unter Mitarbeit von H. Lenz. Band 4. Teil 1, 654
Explosion Flames, Photographic Analysis of, Prof. W. A. Bone, 589
Explosions in Closed Cylinders, Kirkby and Wheeler, 729
External Meatal Notch as a Primitive Character, The, Prof. F. Wood Jones, 458
Extinct Volcanoes of Western Scotland, 619
Extracts from Plant Tissues, Polarographic Analysis with the Dropping Mercury Cathode of, J. Babička, 1013
Eyes, Mineral Content of, H. Ramage and J. H. Sheldon, 376

Fabrician Types of Insects in the Hunterian Collection at Glasgow University, The, Coleoptera, Part 1, R. A. Staig, 1034
False Killer Whale in Ceylon Waters, Dr. J. Pearson, 839
Faraday: E. W. Ashcroft, 323; and Austria, Prof. K. Przibram, 351; and British Association Centenaries, The, 328; and Electrical Science in Russia and the U.S.S.R., W. T. Mitkewich, 359; and French Physicists, Prof. P. Brunet, 346; and his Contemporaries, Engr.-Capt. E. C. Smith, 333; and his Discoveries, A Talking Film of, 541; and Marine Boilers, 1031; and Ørsted, Mrs. Kirstine Meyer, 337; as a Botanist, Dr. R. W. Butcher, 820; Centenary: Celebration at Warsaw, 864; Commemorative Meeting, The, 520; Exhibition, 564; Festival, The, Prof. B. Brauner, 352; India's Debt to, Sir C. V. Raman, 362
Faraday's: "Chemical Manipulation", Sir Robert Robertson and B. A. Ellis, 371; Connexion with Switzerland and Swiss Industrial and Economic Development, Prof. C. E. Guye, 349; Discovery of Electromagnetic Induction, The Modern Electric Age in Relation to, Prof. A. E. Kennelly, 356; London Friends, H. G. Wayling, 482; Observations on the Interia of the Mind, Prof. Fraser Harris, 612; Researches: and the United States, Prof. W. R. Whitney, 353; Italian Physicists and, Prof. V. Volterra, 342; on Magneto-Optics and their Development, Prof. P. Zeeman, 365
Fats, Mechanism of the Synthesis of, at the Expense of Glucides, P. R. Bohn, 770
Fédération des Institutions internationales établies à Genève, The, 182
Feeding Stuffs, Home-grown, Dr. H. E. Woodman, 298
Fermentation, Acceleration of, by Algæ and Sea-water, Dr. Pirrone, 419
Ferranti Scholarship of the Institution of Electrical Engineers, award of the, to W. G. Thompson, 581
Ferro-magnetic Test Pieces, Search for Want of Symmetry and Faults in, J. Peltier, 733
Ferromagnetics, The Specific Heat of, and Ewing's Model of the Magnetic Atom, Dr. J. R. Ashworth, 1003
Ferrous Metallurgy, The Elements of, Dr. J. L. Rosenholtz, 626
Fibre Photography, X-Ray, S. Zeidenfeld, 70
Field: Museum of Natural History, Chicago, Prof. S. H. Langdon and Dr. L. Diels elected Corresponding Members of the, 756; Naturalists' Club of Victoria, Jubilee of the, 668
Fifty-two Years of Research, Observation, and Publication, 1877–1920: a Life Adventure in Breadth and Depth. Prof. H. F. Osborn. Edited by Florence Milligan, 625
Fight Against Disease, Autumn Number, 1072
Film Projection, A New System of, Dr. R. T. A. Innes, 1048
Filtration: An Electro-motive Force of, of Abnormal Value, L. Riéty and G. Salager, 1050; The Electromotive Force of, produced by the Ascent of the Sap in Plants, N. Marinesco 422
Finance, Control of, P. B. Whale, 730
Finland, Geological Map of, 728
Firedamp, Causes of Ignition of, by Permitted Explosives, Grimshaw and Payman 867
Fischer and Bulow's Pyrazole, Constitution of, P. J. Drumm, 162
Fishery Research, Advisory Committee on, Prof. G. C. Bourne appointed Chairman of the, 184
Fitzgerald Oscillators, Atoms and Molecules as, Sir C. V. Raman, 795
Flack, Group-Capt. Martin, Sir Leonard Hill, 496
Flame: Propagation in an Electric Field, Prof. W. A. Bone, R. P. Frazer, and W. H. Wheeler, 274; Temperatures, Jones, Lewis and Seaman, 1081
Flash Discharge, Experimental Investigations on the, G. Valle, 806
Flavelle Medal of the Royal Society of Canada, award of the, to Dr. F. G. Banting, 275
Flights from Chaos: a Survey of Material Systems from Atoms to Galaxies, Dr. H. Shapley, 615
Flint, The Age of, M. Burton, 32
Flood-lighting: Display, Lessons from the, P. Good, 822; in London, 439, 487
Flow at High Velocities, Application of (Optical) Interference to some Problems of, R. Tremblot, 733
Flower Anomalies, Some, and their Mode of Inheritance in Primulas, E. Tschermak, 43
Fluid Motion, 654
Fluides, Mécanique des, Prof. H. Villat, 654
Fluorescence: and Free Neutral Radicals, A Connexion between, Dr. W. A. Waters, 905; Mercury Line Spectrum in, Lord Rayleigh, 905
Fluorine: Determination of, as Calcium Fluoride, E. Carrière and Janssens, 806; The Atomic Weight of, Prof. E. Moles, 966; H. S. Patterson, Prof. R. Whytlaw-Gray, and W. Cawood, 375; The Estimation of, P. Mougnaud, 386; The Heat of Dissociation of, Manohar S. Desai, 34
Fluorite Crystals, On Different Habits of, J. Drugman, 42
Flying: as a Career, Major O. Stewart, 961; Cross-Country, Major O. Stewart, 961; -fish, W. L. Calderwood, 216; Fox in Australia, The, F. N. Ratcliffe, 122
Fœcal Pellets, The Form of, and Specific Identification, Prof. R. Macdonald, 68
Fogs of the Meuse Valley, The Poisonous Effect of the, due to Industrial Emanations, F. Bertyn, 422
Food: Investigation Board, Report of the, 1930, 551; The Preservation of, 551
Foot-and-Mouth Disease Research, Prof. J. M. Beattie, 765
Foreign Pests, Against, 85
Forest: Entomology in India, The Study of, 767; Gardens, J. MacDonald, 915; Travel in the Tropics, 1059
Forestry: Vol. 5, No. 1, 935; in the British Empire, The Inception and Development of, Sir Alexander Rodger, 833; Mycorrhiza in Relation to, Dr. M. C. Rayner, 1011; Practice and Research, A. C. Forbes, 31; Research in Great Britain, F. T. Brooks; J. Ramsbottom, 118
Forests, an Imperial Treasure, 145
Formal Logic, Dr. N. R. Campbell, 620
Forthcoming Books of Science, 631
Fortin Barometer, Casella and Co.'s New Pattern of, 732
Fossil: Plants from the Bokkeveld and Witteberg Beds of South Africa, Prof. A. C. Seward, 1012; Timber from the Sydney Harbour Colliery, R. T. Baker, 806
Fowl, Domestic, Inheritance of Body Weight in, N. F. Waters, 846
France, Le littoral du nord de la, et son évolution morphologique, suivi d'un appendice: L'Évolution du rivage du nord de la France et l'activité de l'homme, A. Briquet, 396
Freiburg im Breisgau University: conferment of honorary degrees upon Lord Rutherford, Prof. Siegbahn, and Prof. Goldschmidt, 756; New Laboratory for Physical Chemistry, 833

French Physicists, Faraday and, Prof. P. Brunet, 346
Freshwater Algæ and Phytoplankton from the Transvaal, G. Nygaard, 316
Fritz, John, Gold Medal, award of the, to Prof. M. I. Pupin, 868
Frog's Gastrocnemius, Myothermic Experiments on the, Prof. A. V. Hill, 805
Frost Injury to Plants, R. Newton and W. R. Brown, 911
Fulani of Northern Nigeria, The, G. W. Webster, 874
Fungi: Entomogenous, T. Petch, 874; Higher, Recent Advances in our Knowledge of the, Prof. A. H. R. Buller, 81; Researches on, Prof. A. H. R. Buller, Vol. 4, 944
Fungus: and Scale Insect, Symbiosis of, J. N. Couch, 119; Sexuality of a, Influence of Yeast Extracts and Concentrates of B Vitamins on the, W. H. Schopfer, 734

γ-Rays, Origin of, Lord Rutherford and Dr. C. D. Ellis, 415, 805
Galactic Rotation, Prof. P. Stroobant, 764
Galapagos Islands, Birds of the, H. S. Swarth, 762
Galaxy and the Solar Apex, Rotation of the, shown by the Radial Velocities of the Helium Stars, P. Stroobant, 846
Gallium in the Organism, Distribution of, C. Levaditi, J. Bardet, A. Tchakirian, and A. Vaisman, 466
Gallnuts as a Chemical Reagent, Dr. M. Nierenstein, 1006
Game Reserves in South Africa, New, Prof. H. B. Fantham, 992
Gamma Rays: Absorption of the Penetrating, by Lead Screens 12-30 cm. thick, A. Piccard, E. Stahel, and F. Dony, 846; Cosmic Rays and, Similarity between, Prof. R. A. Millikan and Dr. I. S. Bowen, 582
Gammarus chevreuxi Sexton, A New Locality for, F. T. K. Pentelow, 797
'Gapes' in Chickens, The Treatment of, Dr. W. R. G. Atkins, 585
Gas Reactions, Heterogeneous, Absolute Rates of, B. Topley, 115
Gaseous Explosions, Limits of, M. Neumann and A. Serbinoff, 1040
Gases, Rare, The Thermal Conductivity of the, M. Curie and A. Lepape, 1050
Gassendi and the Transit of Mercury, 787
Gasteromycetes of Australasia, The, G. H. Cunningham (11). The Phallales (pt. 2), 280
Gaster Siccata B.D.H., British Drug Houses, Ltd., 183
Gauss's Investigations on Electrodynamics, Prof. C. Schaefer, 339
Geiger: Counter, A Counting Device for use with the, Dr. J. C. Jacobsen, 674; Counters, A Method of Recording Coincidences between, Dr. J. C. Jacobsen, 185
Gelatine, Condition of sparingly Soluble Substances in, Dr. T. R. Bolam, 222; Dr. S. C. Bradford; Dr. B. N. Desai, 223
Gene, The, and the Theory of Living Structures, Dr. C. B. Bridges, 991
van Gent's Short Period Variable, H. L. Alden, 641
Géographie, La, the name of, changed to *Terre Air Mer*, 671
Geography: Modern, The Groundwork of, an Introduction to the Science of Geography, Dr. A. Wilmore. Third edition, 955
Geological Survey of India, 885
Geologie: der Steinkohlenlager, A. Dannenberg, 816; Lehrbuch der. Teil 3: Geologische Landerkunde (Regionale Geologie), Prof. F. X. Schaffer. Lief. 1, 956
Geology: A Century of, Prof. J. W. Gregory, 531, 857; Historical, Outlines of, Prof. C. Schuchert. Second edition, 513; of Ardnamurchan, North-west Mull and Coll, The, J. E. Richey and others, 619; Physical, Outlines of, Prof. C. R. Longwell, 513; Plants and, 559
Geometric Considerations for Periodal Analysis, M. Lombardini, 1050
Geometrie, Vorlesungen uber Grundlagen der, Prof. K. Reidemeister, 626
Geometry: Analytical, The Elements of, J. I. Craig. Vol. 1: Straight Line and Circle, 52; and Induction, Foundations of, J. Nicod. Translated by P. P. Wiener, 430
Geophysical: Prospecting: The Principles and Practice of, being the Report of the Imperial Geophysical Experimental Survey, edited by A. B. Broughton Edge and Prof. T. H. Laby, 427; Surveying, Modern Methods of, 634
German: Bunsen Society in Vienna, The, Prof. F. Paneth. Translated by Dr. R. W. Lawson, 94; Glaciation, 394; University System, The, 845
Germany, The Dissemination of Scientific Information in, 833
Giant Crescents: a New Stone Age Industry from South Africa, C. van Riet Lowe, 36
Glaciers, The Melting of, Dr. W. J. Humphreys, 911
Glass: Coloured, as a deterrent to House Flies, Chance Bros. and Co., Ltd., 277; -making, The History of, Sir Richard Gregory, 697; Optical, Manufacture, Recent Developments in, W. M. Hampton and W. N. Wheat, 926
Glasses: Modern, at the Science Museum, 765; The Ultra-Violet Transmission of, P. Gilard, 846
Globin with Hæmatins of various Origins, Combination of, J. Roche and A. Bendrihem, 646
Glow: Discharge, Cathode Phenomena in the, Prof. A. Guntherschulze and F. Keller, 840; -worm, Spectrum of, Dr. L. A. Ramdas and L. P. Venkiteshwaran, 726; -worms, Light of, Dr. M. Perkins, 905
Glozel alleged Antiquities, The, 60
Glucuronic Acid, The Pyranoid Structure of, and of Theophylline Arabinoside, J. Pryde and R. T. Williams, 187
Glutathione, Relation of, to Cell Respiration with special reference to Hepatic Tissue, Sir F. Gowland Hopkins and K. A. C. Elliott, 805
Glykoside: Die, Chemische Monographie der Pflanzenglykoside, Dr. J. J. L. van Rijn. Zweite Auflage von Prof. H. Dieterle, 959
Gmelins Handbuch der anorganischen Chemie: Achte Auflage. System-Nummer 59: Eisen. Teil A, Lief. 3; Teil B, Lief. 3, 657; System-Nummer 26: Beryllium. System-Nummer 58: Kobalt. Teil B: Die Ammine des Kobalts, 816
Gold: Colloidal, Magnetism of, V. I. Vaidhianathan and Balwant Singh, 302; -copper: Alloys, Transformations in the, J. L. Haughton and R. J. M. Payne, 554; Solid Solutions, Physico-Chemical Study of the, N. S. Kurnakow and N. W. Ageew, 554; Organic Compounds of, Gibson and Colles, 840; Resources of the World, Dr. W. Cullen, 4
Goldfish, Scales in, Transformation of, Yasumasa Mori, 119
Golgi Substance, Nature of, D. H. Tennant, M. S. Gardiner, and D. E. Smith, 728
Gondwana System, The, Dr. C. S. Fox, 763
Government Chemist, Report of the, 791
Graf Zeppelin, The Arctic Cruise of the, 490
Graham, George, F.R.S., 1673–1751, 435
Granulobacter pectinovorum, Influence of the Associated Bacteria on the Nitrogen Régime of, M. Korsakova and E. Nikitina, 387
Gravels in the New Forest Area, Age of Certain: N. C. Burkitt, 222; H. J. E. Peake, 377
Gravitation and Electricity, The Unitary Theory of, (3), P. Straneo, 1050
Gravity Anomalies, Major E. A. Glennie, 1004
Gray, John, Jubilee Scholarship, award of the, to G. A. Thompson, 805
Great: Britain, Distribution of Urban Population in, Prof. C. B. Fawcett, 1070; Nebula in Orion, Distance of the, Dr. R. J. Trumpler, 73
Greek Mathematics, A Manual of, Sir Thomas L. Heath, 739
Green Auroral Line, Excitation of the, Prof. J. Kaplan, 304
Greenland: Cod, The, 731; Ice-cap, Thickness of the, 296; Whale and Narwhal, Migrations of the, Dr. R. W. Gray, 798
Grid System, Subsidiary Systems in connexion with the, P. V. Hunter, 633
Grignard's Reagent, Action of, on *N*-methyl Pyrrolidon, R. Lukes, 127
Grotte d'Isturitz, La, I: Le Magdalénien de la Salle de Saint-Martin, Dr. R. de Saint-Périer, 988

Grouse, White Hen, A Protected, 102
Guano, Decomposition of, P. R. v. d. R. Copeman and F. J. Dillman, 682
Guarana, The Active Principle of, G. Bertrand and P. de Berredo Carneiro, 555
Guayra Falls of the Parana, The, E. C. Rashleigh, 549
Gun-cottons, a Method of Studying the Decomposition of, at the Ordinary Temperature, M. Lambrey, 1050
Gyroscope, Mechanics of the, Prof. R. F. Deimal, 289

Hadzapi, The, or Watindega of Tanganyika, Miss D. F. Bleek, 379
Haffkine Institute, Report of the, 1929, 220
Hail Storm, June 14, at Doncaster, N. L. Silvester, 35
Hairs: and Wools, Prof. J. Glaister, 227; So-called, in the Ampullar Organs of Fish Ears, Movements of the, R. E. Bowen, 280
Hakemite Tables of Ebn Jounis, The, J. H. Reynolds, 913
Hamilton, Sir William Rowan: Influence of the Work of, on Modern Mathematical Thought, Prof. A. W. Conway, 198; The Mathematical Papers of, Vol. 1: Geometrical Optics. Edited by Prof. A. W. Conway and Prof. J. L. Synge, 167
Hamilton's 'Characteristic Function', A. S. Ramsey, 167
Hanbury Memorial Medal of the Pharmaceutical Society, Presentation of the, to Prof. H. Thoms, 667
Hand-Spinning in Egypt and the Sudan, Mrs. Grace M. Crowfoot, 71
Hannah Dairy Research Institute, Dr. J. D. Stirling appointed to the Staff of, 81
Harrison's, John, Third Time-keeper, 381
Harvard: Museum Expedition to Australia, The, Prof. J. Stanley Gardiner, 457; University Geological Expedition in the Canadian Rockies, 1929 (3), E. Paréjas, 235
Harvester-thresher Machine Trials, Results of, 754
Haulage Accidents in Collieries, Report on, 101
Hawaii, Biological Research in, C. H. Edmundson, C. M. Cooke, jun., and H. E. Crampton, 36
Hawaiian: Lavas, Radium in, C. S. Piggot, 840; Temples, Dr. W. C. Bennett, 497; Volcano Observatory, Work at the, Prof. T. A. Jaggar, 1036
Hawksley, Thomas, Lecture, The, Ll. B. Atkinson, 865
Health: and Hygiene Charts, Dr. Winslow, with Descriptive Booklet by Prof. V. H. Mottram, 113; and Physik: Sixty Centuries of, the Progress of Ideas from Primitive Magic to Modern Medicine, S. G. B. Stubbs and E. W. Bligh, 939; Ministry of, Annual Report of the, 577; Public, To-day and To-morrow, Dr. W. G. Willoughby, 143
Heat: Engine, A New, J. F. J. Malone, 80; Insulation of Furnaces, J. B. Barnitt and R. H. Heilman, 971
Heavens, The, and the Universe, Prof. O. Thomas. Translated by B. Miall, 244
Hele-Shaw's Method, The Extension of, to Cyclic Movements, Mme. V. Popovitch-Schneider, 386
Helgoland und die Zerstorung seiner Felskuste durch das Meer, O. Pratje, 657
Heliometer, Accuracy of the, Prof. de Sitter, 274
Helium and its Properties, Lord Rutherford, 137
Helix aspersa, the Common Snail, Outgrowths from Pieces of, Prof. J. B. Gatenby, 1002
Henry, Joseph, Edith W. Stone, 542
Hermann, Otto, Medal of the Hungarian Ornithological Society, Award of the, to Dr. W. Stone, 670
Herring and Plankton, Distribution of, R. E. Savage, 1079
Herschel's Mirrors, Sir William, Capt. M. A. Ainslie, 1007
High: Frequency and very High Frequency Currents, The Comparative Biological Properties of, J. Saidman, 1013; Resistance, A Spark Method of Measuring, J. A. C. Teegan, 585; Vacua, Dr. S. Dushman, 72; Voltages, Measurement of, Prof. W. M. Thornton, 875
Hiroshima University, Journal of Science of the, Series B, Div. 1 (Zoology), part 1, 64
Hoba (South-West Africa), the Largest Known Meteorite, Dr. L. J. Spencer, 42
Homo sapiens and African Prehistory, E. J. Wayland, 1003
Hong Kong: Horticultural Society, Occasional Notes of the, No. 1, 146; *Naturalist*, May, 331
Hormones, Œstrus-producing, Dr. G. F. Marrian and A. Butenandt, 305
Horticultural Abstracts, pt. 1, 265
Housesteads National Park, A Suggested, Dr. Vaughan Cornish, 934
Huddersfield Technical College, Dr. J. Ward appointed head of the Department of Civil and Mechanical Engineering, 916
Hudson Bay: and Strait, Navigable Conditions in, 995; Region and the North-West Territories of Canada, Development of the, Dr. Brysson Cunningham, 53
Hull: Museums, Additions made to the, 113; University College, Fisheries Research at, 1032
Human: Body, The, Dr. L. Clendening. Second edition, 173; Embryology, Dr. G. Streeter, 804; Genetics, Research in, a Committee to consider, 183; Population, Discussion on, 577; Scale, From the, to the Terrestrial Scale, R. Wavre, 236; Skeleton: The Origin of the, an Introduction to Human Osteology, Dr. R. Broom, 4; Skulls and Bones from the Naga Hills, Dr. B. S. Guha and P. C. Basu, 762
Humanity: Science and, 505; under the Hammer, Lt.-Col. E. Kitson Clarke, 790
Humidity: Control and Entomological Problems, Dr. P. A. Buxton, 1079; in the Upper Air, Graphical Indication of, Dr. C. W. B. Normand, 583
Hunger and Love, L. Britton, 475
Hurricane in British Honduras, 543
Hydraulics, A New Principle of, M. Golaz, 646
Hydrazine: and Semicarbazide, The Oxidation of, by Potassium Iodate, V. Hovorka, 1013; Ultra-Violet Absorption and Raman Effect for, S. Imanishi, 64
Hydrocarbons: Slow Combustion of, Dr. R. Spence, 873; The Peroxidation of, during Combustion in Air, Dr. E. Mardles, 116
Hydro-Electric Power Development, Influence of Modern, on the British Coal Trade, Dr. Brysson Cunningham, 397
Hydrogen: Absorption of, The Critical Increment of the, on Amorphous Carbon at 400°-520° C., Dr. F. E. T. Kingman, 272; Activated Adsorption of, by Zinc and Chromium Oxides, Prof. H. S. Taylor, 636; and Oxygen, Combination of, W. L. Garstang and H. L. Hinshelwood, 1044; Influence of, on Chemical Changes in Silica Vessels, Prof. M. W. Travers, L. E. Hockin, and T. J. P. Pearce, 66; Iodide, Photochemical Decomposition of, Rollefson and Booher, 72; Ion Concentration: of Natural Waters, A New Colorimetric Method for measuring the, Daphne L. Coulston, 316; of Sea-water, Variations of the, Daphne L. Coulston, 316; The Measurement of, Dr. J. Grant, 852; -Nitrous Oxide Flame, Spectrum of the, Prof. A. Fowler and J. S. Badami, 881; Resonance Spectrum of, Prof. K. R. Rao and J. S. Badami, 585; Sulphide and Sulphur Dioxide, Reaction between, Prof. Basrur Sanjiva Rao and M. R. Aswathnarayana Rao, 413
Hydrogenating Cracking of Phenols, Mode of Action of Dehydrating Catalysts in the, A. Kling and D. Florentin, 1050
Hydrogenation, Catalysed, The Velocity of, A. Kailin and H. C. Hardt, 467
Hydrographic Surveying, Modern, The Physical Basis of, A. L. Shalowitz, 1014
Hydroxylic Compounds, Identification of, Morgan and Pettet, 37
Hygiene Exhibition, An International, at Dresden, 298
Hyperbolics: Elementary, for Technical and other Students; especially adapted to the Requirements of Beginners, M. E. J. Gheury de Bray. 2 vols., 1026
Hyperfine Structure: Isotopic Displacement in, J. H. Bartlett, Jr., 408; of Lines, Charges of Intensity in the, H. Schuler and J. E. Keyston, 911; of Thallium II, Dr. J. B. Green and J. Wulff, 409

Ice: Cooling Effects of, on the Oceans, E. H. Smith, 840; Rinks, Artificial, 489
Iceland, the Petrology of (2), G. W. Tyrrell and M. A. Peacock, 881
Identification Method, A New, Dr. T. Poole, 904
Idu (Japan) Earthquake of Nov. 26, 1930, The, Dr. C. Davison, 552

Illumination: and Tree Growth, Dr. W. R. G. Atkins and Florence A. Stanbury, 191; Congress, The International, 588, 642; Dr. A. R. Meyer elected President for 1934, 643; Device for Microscopy, A New, E. Leitz, 1010; in Factories, Dr. N. Goldstern and Dr. F. Putnoky, 1080
Immunity: Reactions, The Study of Specific Combination in, J. R. Marrack and F. Campbell Smith, 1077; Studies in, Prof. J. M. Beattie, 888
Imperial: Bureau of Soil Science, resignation of the Deputy Directorship of the, by Dr. A. F. Joseph, 220; Cancer Research Fund, Report of the, 931; Horticultural Conference, Proceedings of the, 220; Institute, Annual Report, 16; Sugar Cane Research Conference, 1931, 160
India: Archæological Service in, Proposed Changes in the, 216; Education in, in 1928–29, 197; Entomology in, The Study of, 767; Geological Survey of, 885; Irrigation in, 1928–29, 37; Lectures on the Races and Cultures of, 216; Survey of, Report of Map Publication and Office Work of the, 1929–30, 30; Zoological Survey of, 849
Indian: Archæology in Eastern Canada, W. J. Wintemberg, 1005; Butterflies, Mimicry in, Dev Raj Puri, 459; Coal, Utilisation and Conservation of, C. H. McCale, 219; Education Problem, The, J. C. Ghosh, 681; Ethnography, 50; Insects, Catalogue of, Part 18, H. E. Andrews, 867; Institute of Science: F. N. Mowdawalla appointed Professor of Electrical technology in the, 197; Extension of Service of Dr. M. O. Forster as Director; appointment of Dr. V. Subrahmanyan as Professor of Biochemistry, 1049; *Journal of Veterinary Science and Animal Husbandry*, Part 1, 299; Mosses, Census of, P. Brühl, 182; Place-names, Rai Bahadur Hira Lal, 839; Terracottas, K. de B. Codrington, 414
Indians: of Pecos Pueblo: The, a Study of their Skeletal Remains, Dr. E. A. Hooton, and others, 740; We, the Passing of a Great Race. Being the Recollections of the last of the Great Indian Chiefs, Big Chief White Horse Eagle, as told to Edgar von Schmidt-Pauli. Translated by C. Turner, 891
India's Debt to Faraday, Sir C. V. Raman, 362
Indium and Thallium, Arc Spectrum of, Fine Structure in the, Dr. A. L. Narayan, 675
Indo-China, the Tectites of, A. Lacroix, 386
Industrial: and Social Economics, 773; Problems of To-day, Some, S. Rowntree, 331
Industry: and Rationalisation, Research in, A. Y. Enstrom, 122; Creative Science and, 317; University Training in Relation to, 1017; Value of Research Methods in, Steatite and Porcelain Products, Ltd., 1033
Infection by Air, Experiment on, A. Trillat, 235
Infections: Ectromelia, The Causative Organism in, J. E. Barnard and W. J. Elford, 917; Diseases, The Problem of making Conditions unsuited to, Prof. N. J. G. Smith, 801
Infra-Red: Radiation from an Engine, An Investigation of, S. Steele, 185; Rays, Therapeutic Uses of, W. A. Troup, 953
Insect-borne Diseases, Disappearance of, from Britain, Dr. Ll. Lloyd, 798; Control in the United States and Canada, 146; Metamorphosis, Effects of Inadequate Feeding on, C. Dover, 303; Dr. Hem Singh Pruthi, 869; Relations of Plant Virus Diseases, Dr. Kenneth Smith, 915; Vectors and Virus Diseases of Plants, Dr. K. M. Smith, 379
Insects: and Climate, 689; specially Injurious to Cultivation in French Switzerland, J. and L. Deshusses, 467
Instinct and Intuition: a Study in Mental Duality, G. B. Dibblee, 51
Instituts Nationaux à l'Étranger, The Organisation and Activities of, 63
Insulin: Molecular Weight of, Sjogren and Svedberg, 380; Therapy, British Drug Houses, Ltd.; Allen and Hanburys, Ltd., 461
Intelligence, Environment, and Heredity, Prof. R. W. Wilcocks, 801
Interferential Level, An, without an Air Bubble, C. Fabry, 466, Internal: Combustion Engine: Power and the, Prof. W. E. Dalby, 886; The, and its Performance, W. A. Tookey, 634; The High-speed, H. R. Ricardo. New Edition, 886; Secretion, The Physiology of, Sir E. Sharpey-Schafer, 437, 441
International: Aspects of Agriculture, 597; Astronomical Union (Union Astronomique Internationale) Report of Commission 3: Atlas céleste, E. Delporte, 690; Bibliographical Guide, Forthcoming, 936; Congress for the Testing of Materials, 643; Dr. W. Rosenhain elected President for 1935, 644; Congress of Pure and Allied Chemistry, the Forthcoming, 901; Congress of the History of Science and Technology, The, Dr. T. Greenwood, 77; Council of Scientific Unions, Dr. G. Hale elected President of the, 111; Dairy Congress, The Ninth, 145; Geological Congress, Postponement of the, till 1933, 61, 698; Illumination Congress, The, 588, 642; Dr. A. R. Meyer elected President for 1934, 643; Institute of African Languages and Cultures, Grant to the, by the Rockefeller Foundation, 265; Agriculture, The, Dr. A. Hobson, 737; Polar Year, A Second, 754; Union for Geodesy and Geophysics. Section of Terrestrial Magnetism and Electricity. Comptes rendus de l'Assemblée de Stockholm, 1035; Union of Physics, Brussels Meeting, 1931, 485; Standards of Lighting, 1083
Intestinal Juice and of the Pancreatic Juice, The Proteolytic Ferments of the, E. Le Breton, F. Mocoroa, and E. Stulz, 422
Intrammon and Locron, Two New Reagents, 1035
Iodide, The Oxidation of, by Persulphate, King and Jacobs, 121
Ionised Gases and the Working of Valves with Positive Grid, and V. Ionescu, 882
Ions, Negative: Prof. H. D. Smyth, 677; Photoelectrons and, Dr. J. L. Hamshere, 871
Irish Radium Committee, Report for 1930, 756
Iron and Steel, Non-Metallic Inclusions in, Dr. C. Benedicks and H. Lofquist, 856; Compounds in Yeast Complex, Oxidation Reduction Potential of, T. B. Coolidge, 223; Dipped into Aerated Saline Solutions, the Protection by Cathode Polarisation, E. Herzog and G. Chandron, 882; Nitride, Atomic Hydrogen occluded in, Shun-ichi Satoh, 457; The Passivity of, U. R. Evans, 1062
Islam, Sociology of, An Introduction to the, R. Levy, 951
Isotope Effect in the Band Spectrum of Lithium Hydride, Prof. G. Nakamura, 759
Isotopes: of Lead: Nuclear Moments of the, Relative Values of the $g(L)$ Factors of Pb(207) and Tl, Prof. J. C. McLennan, M. F. Crawford, and L. B. Leppard, 301; of Lithium, Sodium, and Potassium, K. T. Bainbridge, 876
Isotopes, Prediction of, H. L. Johnston; H. C. Urey, 498
Italian: Physicists and Faraday's Researches, Prof. V. Volterra, 342; Royal Geographical Society, Gold Medal and Diploma of the, Presentation of, to Sir Hubert Wilkins, 184
Ives, Frederick, Medal of the Optical Society of America, award of the, to Prof. T. Lyman, 834

Janssen, Jules, 1824–1907, 239
Japan, Larval Freshwater Shrimps from, Dr. Zu Yokoya, 874
Japanese: Earthquake of 1923, The, Dr. C. Davison, 989; Morning Glory, Genetics of, Yoshitaka Imai, 497; Nematodes, Dr. Shigemoto Imamura, 586
Jaws and Teeth, Evolutionary Tendencies in the, Prof. G. Elliot Smith, 501
Jeanne d'Arc, The Trial of, a Complete Translation of the Text of the Original Documents, with an Introduction, by W. P. Barrett, 284
Jet-wave Rectifier, The, J. Hartmann, 156
Jewels, Pivots and, V. Stott, 273
Joan of Arc, The Psychological Problem of, 284
Jolliffe and Banks, Contractors, The Work of, H. W. Dickinson, 698
Joshua: Judges, Prof. J. Garstang, 938
Jumping Negative Glow, The, W. A. Leyshon, 795
Jungfraujoch Scientific Station, The, 817
Jungle-fowl at the Zoological Society's Gardens, 180

Jupiter: Rapid Current on, B. Peek, 192; The Faint Outer Satellites of, Prof. M. Wolf, 912
Jupiter's Satellites, Mutual Eclipses of, 876

Kansas Permian Insects, Dr. R. J. Tillyard, 414
Kaolin Minerals, C. S. Ross and P. F. Kerr, 875
Karité Butter, Composition of, J. Bougault and G. Schuster, 682
Katwe Crater-lake, The, Uganda, E. J. Wayland, 977
Kelvin Lecture, Prof. W. L. Bragg, 210, 248
Kelvin's "On the Clustering of Gravitational Matter in any Part of the Universe", Dr. M. C. Grabham, 793
Kenya: Colony, The Stone Age Cultures of, Dr. L. S. B. Leakey. With Appendices by J. D. Solomon, C. E. P. Brooks, A. T. Hopwood, H. C. Beck, and M. Connolly, 1019; Early Man in, 1019
Keratin Molecule, Constitution of the, J. B. Speakman and Mercia C. Hirst, 1073
Kew, Royal Botanic Gardens, J. S. L. Gilmour appointed assistant director of the, 756
Kidney, Work of the, in the Production of Urine, H. Borsook and H. M. Winegarden, 83
Kikuyu Girls, The Marriage of, Dr. L. S. B. Leakey, 696
Kilimandjaro: Der, sein Land und seine Menschen, Dr. W. Geilinger, 956
Kish, Human Remains from, Dr. L. H. Dudley Buxton and D. T. Rice, 798
Knowledge: A New Summary of, Prof. F. S. Marvin, 937; Modern, An Outline of, edited by Dr. W. Rose, 937
Kohle: Der Chemie der, Dr. W. Fuchs, 1024; Entstehung, Veredlung und Verwertung der, W. Petrascheck and others. Herausgegeben von Prof. K. A. Redlich, Prof. J. C. Breine und H. Tropsch, 1024
Krypton and Xenon, F. J. Allen and R. B. Moore, 380

Labrador, Coast of, Uncharted State of Part of the, Sir Wilfred Grenfell, 635
Lake: Baikal, Some New Marine Infusoria Symbiotic in Molluscs of, E. Cheisin, 163; Gusinœ, Transbaikalia, Periodic Variations in the Level and in the Chemical Composition of the Water of, A. Zachvatkin, 422
Lancashire and Cheshire Coal Research Association, opening of New Laboratories of the, 580
Lange (Prof. J.), translated by Charlotte Haldane, Crime as Destiny: a Study of Criminal Twins, 630
Lankester, late Sir Ray, Work of the, Prof. E. S. Goodrich, 64
'Lapides palmati', The, mentioned in the "Historia Naturalis" of the Elder Pliny, Dr. K. C. Bailey, 672
La Tène Spear-head from the Thames, A late, T. D. Kendrick, 586
Lavoisier, Priestley and, Sir Philip Hartog, 797
Law, Oriental and Tropical, The Study of, 265
Lead: Alloys: Effects of Cold-rolling and of Heat-treatment of some, H. Waterhouse and R. Willows, 502; The Spectrographic Assay of some, D. M. Smith, 554; and Iron, Penetrating Corpuscular Radiation in, Absorption and Diffusion of the, B. Rossi, 806; Isotopes of, Nuclear Moments of the, Relative Values of the $g(I)$ Factors of Pb(207) and Tl, Prof. J. C. McLennan, M. F. Crawford, and L. B. Leppard, 301; The Spectrographic Assay of some Alloys of, D. M. Smith, 802
Leaf Fall in the Tropics, R. E. Holtum, 798
Leather Crafts Manual, Ivy Evelyn Norman and P. I. Smith, 1060
Leathers, Examination of Dyed, in Cases of alleged Dermatitis, T. Callan and N. Strafford, 733
Leeds University: Additional Grant by the West Yorkshire Coal Owners' Association, 41; conferment of Honorary Doctorates, 80; institution of a Diploma in Public Administration, 278
Leibniz: The Monadology of, with an Introduction, Commentary, and Supplementary Essays, Dr. H. Wildon Carr, 136
Leicester Museum and Art Gallery, Extension of the, 936
Lemna: Chemical Composition of, as a Specific Character, V. Vernadskij and A. Vinogradov, 770; The Chemical Composition of, as Characteristic of the Species, V. Vernadskij and A. Vinogradov, 882
Lens, The Calculation of a, G. Vitali, 1050
Lepidocyclina, *L. hamiltonensis*, and *L. howchini*, New Species of, F. Chapman and Irene Crespin, 683
Lepidosiren, The Double Lateral Line of, J. T. Cunningham, 377
Lepomis, Relative Effectiveness of Spectral Radiation for the Vision of the Sun-fish, H. Grundfest, 555
Let's Help! a Collection of Good Causes, Sir Charles Bright, 989
Levigator with a Motionless Liquid Medium, A. E. Joukowsky, 734
Liapounov, A. M., 1857–1918, A. J. Pressland, 138
Lichenin, Prof. J. Reilly, M. Hayes, and P. J. Drumm, 162
Life: and Matter, Sir Peter Chalmers Mitchell, 723; Outlines of General Biology, Sir J. Arthur Thomson and Prof. P. Geddes. 2 vols., 1056; Science and Philosophy of, Prof. J. Ritchie, 1056; The Origin of, G. Rumbold. Second impression, 243
Light: Intensities, The Translation of, into Sound Intensities, G. Fournier, 234; Intensity in Two Common Vegetation Types in Tropical Africa, Photochemical Measurements of, J. Philip, J. D. Scott, and J. Y. Moggridge, 162; Quanta, Spin of, Sir C. V. Raman and S. Bhagavantam, 727; Scattered by Liquids, The Fine Structure of Spectral Lines of, S. Rafałowski, 495; -scattering: Doppler Effect in, Sir C. V. Raman, 636; in Liquids, S. Venkateswaran, 870; Spin of, Experimental Demonstration of, Sir C. V. Raman and S. Bhagavantam, 576; The Angular Momentum of, Sir C. V. Raman, 545; The Deflection of, in the Sun's Gravitational Field, Prof. E. Freundlich, 993; The Penetration of, through Successive Layers of Tissue Paper, Dr. W. R. G. Atkins, 545; Transmission through Fog, H. G. Houghton, 1043; Velocity of: Dr. V. S. Vrkljan, 269; from the Spiral Nebulæ, G. Strömberg, 587
Lighting: International Standards of, 1083; Units, Testing of Combinations of, D. C. Rose, 1034
Lightning: Ball, Charged Aerosols and, W. C. Reynolds, 584; Branching of, Dr. B. F. J. Schonland and Dr. T. E. Allibone, 794; Major J. L. P. Macnair, 969; Correlations between the Field Changes due to, and the Appearance of the Flashes, E. L. Halliday, 200; Discharge, Duration and Magnitude of a, R. S. J. Spilsbury, 872; Phenomena, Dr. B. F. J. Schonland, 799; Unusual, H. E. Beckett and A. F. Dufton, 189; Capt. C. J. P. Cave, 378
Liming and Fertility, 1080
Limnological Laboratory, Reports from the, (2), R. Southern and A. C. Gardiner, 1013
Limonites, Artificial Magnetisation of, F. Loewinson-Lessing, V. Mitkevitch, amd A. Turcev, 127
Linear Partial Differential Equations, An Operational Method for the Solution of, W. O. Kermack and W. H. McCrea, 882
Linnæus, The Influence of, upon Gilbert White, Dr. K. Hagberg, 332
Linseed Oil, Composition of, N. E. Cocchinaras, 1086
Lion Farm, A, at El Monte, U.S.A., 578
Lipetsk Area, The Origin of the Ferrous Deposits in the, A. Archangelskii and D. Perkin, 163
Lipoid Nephrosis: Blood Serum in, Some Physical Properties of the, C. Achard and A. Boutaric, 315; The Physical Properties of the Serum Proteins and of the Hydropic Serosities in, C. Achard, A. Boutaric, and A. Arcand, 646
Liquation Phenomena in a Coinage Bronze, A. Borloz, 734
Liquid: Drops in Electric Fields, Dr. W. A. Macky, 799; Mixtures, Diamagnetism of, V. C. G. Trew and Prof. J. F. Spencer, 152; Dr. H. Buchner, 301; Prof. E. van Aubel, 455; S. Ramachandra Rao and G. Sivaramakrishnan, 872
Liquids, Viscosity of, Prof. G. W. Stewart, 727; Prof. E. N. da C. Andrade, 835
Lister Institute: Dr. T. F. Macrae appointed a Research Student in Biochemistry at the, 197; Report for 1931, 1009
Lithium: Constitution of, Dr. F. W. Aston, 149; Hydride, Isotope Effect in the Band Spectrum of, Prof. G. Nakamura, 759; Metallic, The Excitation Potentials of, Dr. H. W. B. Skinner, 114

Lithothamnion in the South Indian Cretaceous, Occurrence of, Prof. L. Rama Rao, 225, 873
" Live and let Live ", 329
Liverwort, A, as Pioneer on Burnt Forest Land, 37
Load-gauge, A remote Electrically Recording, for Wheel-impact Measurements, Dr F. Aughtie, 918
Lobatsi-Linokana Area, The Herpetological Fauna of the, J. H. Power, 126
Locomotive Laboratory, A, 63
Locomotives, Articulated, Prof. L. Wiener, 289
Locron, Intrammon and, two new Reagents, 1035
Logarithmic Potential, Certain Problems on the Limits of the Theory of, E. Okhlopkova, 43
Logarithms, Addition-Subtraction, to Five Decimal Places, L. M. Berkeley, 91
Logaritmer of Antilogaritmer, Femcifrede, A. K. Erlang, Udgivet ved R. E. H. Rasmussen, 91
Logic: Formal: A Treatise of, its Evolution and Main Branches, with its Relations to Mathematics and Philosophy, Prof. Jørgen-Jørgensen. 3 vols., 1021; The Development of, Dr. T. Greenwood, 1021; Textbook of, Prof. A. Wolf, 6
L'Ologénèse: nouvelle théorie de l'évolution et de la distribution géographique des êtres vivants, Prof. D. Rosa. Adapté de l'italien par l'auteur, 429
London: and the Advancement of Science, 687; and the British Association, 687; City of, Science in the, Engr.-Capt. E. C. Smith, 515; Mathematical Society, election of officers, 868; Skull, The, C. N. Bromehead, 118; University: Bequest by J. F. H. Knight, 80; Conferment of a Doctorate, 124; Prof. C. Burt appointed Professor of Psychology at University College; renewal of the Sir George Jessel Studentship in Mathematics to T. E. Garstang; and award of the same Studentship to H. Kestelman, 161; conferment of Doctorates, 313; Dr. F. C. Benham appointed University Reader in Commerce, 804; R. J. V. Pulverstaft appointed University Reader in Pathology; conferment of Title of Reader on Dr. Nora Edkins, 805; conferment of Title of Professor on F. W. Twort, Dr. H. A. Harris, and Dr. F. A. P. Aveling, and that of Reader in Eugenics on Miss E. M. Elderton, 975; conferment of Honorary Doctorates, 1011
Longshaw Estate, Acquisition of the, by the National Trust, 29
Lord Mayor's Show, Progress of Industry aided by Science illustrated in the, 824
Loudspeaker Frequency Response Curves, Subjective Interpretation of, in terms of Loudness, D. A. Oliver, 268
Loud Speakers, Lanchester's, 669
Low Temperature Carbonisation Test, 841
Lubricating Layers, Adhesion of, to Metals, A. Boutaric and R. Amiot, 882
Ludicrous, The Paradox of the, Prof. S. S. Seward, 988
Lunar Circles, 416

d-Mannitol and *d*-Mannose, An X-ray Examination of, G. W. McCrea, 882
d-Mannose, The Oxidation Products of, by Ammoniacal Copper Oxide in the presence of Air, at the Ordinary Temperature, J. Parrod and Mlle. Y. Garreau, 1050
Macdonnell Ranges, The, C. T. Madigan, 1006
Machine Drawing and Design: a Textbook of Intermediate Standard for Engineering Students, W. Abbott, 962
Magdalenian Deposits near Frangy (Haute Savoie), Discovery of, A. Jayet and G. Amoudruz, 1087
Magical Belief and Practice, 204
Magnesium: Alloys, Protection of, against Corrosion, H. Sutton and L. F. Le Brocq, 502; Pure, Preparation of, by Sublimation, J. Hérenguel and G. Chaudron, 1043
Magnetic: Birefringence, A New Type of, Sir C. V. Raman and S. W. Chinchalkar, 758; Field, Alternating High-Frequency, A Method of Measuring an, F. Esclangon, 882; Phenomena: an Elementary Treatise, Prof. S. R. Williams, 623; Polarisation, Rotatory, Prof. E. van Aubel, 1004; Poles, Isolated Quantised, Prof. O. W. Richardson, 582
Magnetisation, Energy of, A New Relation between Electrical Resistance and, Prof. W. Gerlach and E. Englert, 151
Magnetism: and Electricity: School Certificate, Dr. H. Toms, 431; E. Nightingale, 959; Electricity and, A Connexion between, Dr. P. A. M. Dirac, 586; Modern Views on, Prof. W. Peddie, 623
Magneto: -Electric Saturation Effect, The, Dr. O. E. Frivold and S. Koch, 675; -Optics and their Development, Faraday's Researches on, Prof. P. Zeeman, 365
Maize: in South Africa, A. R. Saunders, 1060; Supernumerary Cell Divisions in, G. W. Beadle, 191
Maladies, L'Esprit et ses, Dr. M. Nathan, 6
Malaria in South Africa, Prof. N. H. Swellengrebel, 497
Malarial Infection in Human Beings, The Prevention of, Col. S. P. James, W. D. Nicol, and P. G. Shute, 404
Malaya, Rubber Research Institute of, Report of the, 880
Malayan *Aleurites Montana*, Oil from, and the Properties of Hong Kong oil, T. H. Barry, 1086
Maleic Acid into Fumaric Acid, A Possible Transformation of, H. Saini and J. Weiglé, 235
Mallard, Eclipse Plumage in the, Violet K. Tallent, 672
Mammals: Certain Extinct, The Auditory Region in, Dr. van der Klaauw, 910; of an Island Group (Pityusa), Dr. O. Koller, 414
Mammoth Remains, Fossilised, near Nottingham, 993
Man: and the Primates, Prof. A. H. Schultz, 1043; and the Stars, Prof. H. T. Stetson, 615; Early, His Origin, Development, and Culture, Prof. G. Elliot Smith, Sir Arthur Keith, Dr. F. G. Parsons, M. C. Burkitt, H. J. E. Peake, Dr. J. L. Myres, 951
Manchester University, conferment of honorary degree on Prof. E. Fiddes and Prof. F. E. Weiss, 916
Manganese, An Electro-Colorimetric Method for the Determination of Small Quantities of, K. Nenadkevic, 770
Mann und Weib: Die Beschneidung bei, ihre Geschichte, Psychologie und Ethnologie, F. Bryk, 91
Manoa, Social Organisation in, Miss Margaret Mead, 414
Man's: Family Tree, The Construction of, Sir Arthur Keith, 590; Remote Ancestry, Prof. G. Elliot Smith, 4
Manured or Artificially Fertilised Soil, Biological Value of the Products of, G. Tallarico, 595
Marine: Algæ from the Pacific, W. A. Setchell and N. L. Gardner, 191; Biology: and the Problems of the Fishing Industry, The Correlation between, Dr. C. von Bonde, 801; Contributions to, 172; Boiler Design: Charts and Data on, a Summary of the Standard Formulæ in Chart Form with Tables and Notes, H. C. Walker, 962; Boilers, Faraday and, 1031; Engineers, Institute of, *Transactions* of the, 63; Fauna of the Plymouth District. Second edition, 936
Marugin Warfare, W. L. Warner, 910
Mason and Dixon's Line, Col. T. T. P. Luguer, 995
Massachusetts Institute of Technology, Research Work at the, 384
Mass Production, Sir Eric Geddes, 182
Materials: and Structures: a Text-book for Engineering Students, Dr. E. H. Salmon. Vol. 1: The Elasticity and Strength of Materials, 617; Strength of, Prof. S. Timoshenko. 2 parts, 617
Mathematical: Analysis, Numerical, Prof. J. B. Scarborough, 962; Ancestry, Our, Prof. H. W. Turnbull, 739
Mathematics: Actuarial, An Elementary Treatise on, H. Freeman, 286; Elementary, Craftsmanship in the Teaching of, F. W. Westaway, 950; for Actuaries and Others, Dr. J. Wishart, 286; The Foundations of, and other Logical Essays, F. P. Ramsey. Edited by R. B. Braithwaite, 620; The Teaching of, 950
Mathématique, Leçons sur la théorie, de la lutte pour la vie, Prof. V. Volterra. Rédigées par M. Brelot, 963
Mathematischen Physik und Technik, Angenäherte und symbolische Lösung der Differentialgleichungen der, Prof. N. M. Kryloff, 963
Matriarchy in the Malay Peninsula and Neighbouring Countries, G. A. de C. de Moubray, 624
Matter: and Radiation, Prof. F. G. Donnan, 290; Life: Mind: A. Eagle; W. W. L., 906; Dr. W. D. Lighthall, 907; Dr. M. Copisarow, 1042; The Annihilation of, Sir James Jeans, 100, 103; The Properties of, W. H. Spikes, 396

Maxillo Facial Correlations, A. L. Perier, 734
Maxwell: James Clerk, Centenary of the birth of, 487, 604; a Commemorative Volume, 1831–1931. Essays by Sir J. J. Thomson and others, 607; and Modern Theoretical Physics, Prof. Niels Bohr, 691
Measurement: Standards of, their History and Development (Guthrie Lecture), Sir Richard Glazebrook, 17
Mécanique, Exercices de, H. Beghin and Prof. G. Julia. Tome 1, Fasc. 2, 514
Mechanics, Intermediate, D. Humphrey. Vol. 2: Statics and Hydrostatics, 244
Medical: Pioneers in Science, Dr. D. F. Fraser-Harris, 864; Research Council: appointment of a Therapeutic Trials Committee, 217; Lord Dawson of Penn and Prof. E. Mellanby appointed members of the, 184; Tables of the Registrar-General's Statistical Review, 1930, 936
Medicinal Ions, The Elective Fixation of, by the Electro-Magnet, D. la Tour du Pin, 199
Medicine: Curative, Science and (Stephen Paget Memorial Lecture), Dr. H. H. Dale, 499; History of, 939; in Massachusetts, A Brief History of, Dr. H. R. Viets, 135
Mediums, Some Modern, T. Besterman, 92
Medizin des Rinascimento, aus der, An der Hand des "Leben von Benvenuto Cellini" nach der Übersetzung Goethes, Prof. P. Strassmann, 173
Megascolides australis, the Largest Known Earthworm, C. Barrett, 669
Melanism in Moths, Inheritance of, A. W. McKenny Hughes, 496
Mellon Institute, The, 418
Membrane Behaviour, Studies in, (1), W. L. Francis, 1049
Mendelian Factor for Flower Colour, Chemical Effect of a, Hon. Mrs. M. W. Onslow, 373
Mental: Defective: The, a Problem in Social Inefficiency, Dr. R. J. A. Berry and Dr. R. G. Gordon, 954; Deficiency, Sterilisation and, 129; Diseases, Joint Board of Research for, Birmingham, Report of the Laboratory of the, 407; Nursing (Simplified), Dr. O. P. N. Pearn, 892
Mercury: Band Spectrum in Fluorescence, Lord Rayleigh, 724; Cadmium, and Zinc, The Forbidden Lines in the High Frequency Discharge of, J. Okubo and E. Matuyama, 224; Derivatives of Divalent Bromo-Phenols, M. Amadori, 647; in Vegetable Tissues, A Method for detecting, D. Petri, 647; Large Drop of, Measurements of the Height of a, R. S. Burdon, 456
Mercury: Motion of the Perihelion of, Dr. J. K. Fotheringham, 841; Photographs of, Mme. G. Camille Flammarion, 82; Transit of, Gassendi and the, 787
Metacresol, The Direct Bromination of, G. Darzens and A. Lévy, 555
Metallurgical Spectrum Analysis, A. A. Fitch, 802
Metals: Dissolved, Estimation of, F. Twyman and C. S. Hitchen, 587; Electrical Conductivity and Optical Absorption in, E. H. Hall, 555; Impurities in, their Influence on Structure and Properties, Dr. C. J. Smithells. Second edition, 627; Institute of, Journal of the. Vol. 44, 514; Microscopic Examination of, by Polarised Light, Dr. M. v. Schwarz, 800; of the Hydrogen Sulphide Group, Separation of the Earth Acids from, E. F. Waterhouse and W. R. Schoeller, 845; Overstrain of, and its Application to the Auto-Frettage Process of Cylinder and Gun Construction, Major A. E. Macrae, 49; The Spectra of, obtained by Explosive Reactions, T. Tucholski, 126
Meteor, A Daylight, 461
Meteoric: Hypothesis for the Origin of the Solar System, Abbé Moreux, 729; Stone from Suwahib, Arabia, A New, W. Campbell Smith, 977
Meteorite Craters: at Henbury, Central Australia, The, A. R. Alderman, 977; in Central Australia, Contents of, 994
Meteorological: Developments important to Agricultural Research, E. G. Bilham, 667; Instruments, Negretti and Zambra's, 670; Office, Annual Report of the Director of the, 753
Meteorology, A Century of, Sir Napier Shaw, 925
Meteors, The Leonid, 841, 912, 972, 1007
Methane and Ethane, The Slow Combustion of, Prof. W. A. Bone, 188; Dr. E. Mardles, 304
Methyl: Alcohol, Heat of Combustion of, F. D. Rossini, 555; -Guanido-Oxalic Acid (Creaton) as a Constituent Part of Muscles, V. Gulevitch, 127
Methylene Blue: in Gelatin, Diffusion and Cataphoresis of, Mlle. Suzanne Veil, 1013; Stain for Yeast Cells, Fink and Weinfurtner, 306
Mexican: Hairless Swine, E. Roberts and W. E. Carroll, 866; Jacana, Incubation of the, A. H. Miller, 306
Mexico, Ancient, Pottery of, E. Noguera, 459
Micelle, Determination of the Charge of the, Mlle. Sabine Filitti, 386
Michelson-Morley Experiment, Repetition of the, Prof. G. Joos, 729
Microcalorimeter: Adiabatic, Application of the, to the Determination of the Heat of Adsorption and of Vaporisation, W. Swietolawski and Mlle. E. Bartoszewiczowna, 126; An Adiabatic, adapted to the Measurement of the Specific Heat of Solid and Liquid Substances, W. Swietolawski, Mme. M. Rybicka, and Mme. W. Solodkowska, 126
Micro-organisms: Formation of New Stable Races of, under the Influence of X-Rays, G. A. Nadson and G. Filippov (2), 422; (3), 467
Microscopy: A New Illumination Device for, E. Leitz, 1010; Some Recent Developments in, Prof. L. C. Martin, 833
Mikrokosmos, October, 756
Milk Diet for Rats, 306
Milky Way, Beyond the, Sir James Jeans, 592, 821, 825
Mind, On the Nature of, Dr. C. S. Myers, 744
Mineral: Frequencies, Heavy, Accuracy in Percentage Representation of, A. L. Dryden, Jr., 422; Industry, Problems of the, Dr. E. F. Armstrong, 508; Names, New, Dr. L. J. Spencer, 42
Mineralogical Society, election of Officers, 834
Minerals in Modern Industry, Dr. W. H. Voskuil, 508
Mira Ceti, The Theory of the Variability of the Family of, G. Armellini, 646
Mitogenetic Radiation acting on the Multiplication of Bacteria, The Hypothesis of, Mlle. Choucroun, 316
Moissan, Henri, A Monument to, 679
Molecular: Spectrum and the Structure of the Molecule: Simple Relations between the, Dr. H. Deslandres, 199, 315; Weight Determinations, Le Fèvre and Webb, 38
Molecules: Atoms and, as Fitzgerald Oscillators, Sir C. V. Raman, 795; Constitution et thermochimie des, A. et M. Gosselin, 92; Organic, and Surfaces, Collision between, F. O. Rice and H. T. Byck, 228
Molybdenum Trioxide, Crystal Structure of: a Correction, Nora Wooster, 35
Molybdo-octocyanides, G. A. Barbieri, 647
Mongolian Wild Horses at the Zoological Society's Gardens, 792
Moniezia expansa, Life-Cycle of, D. F. Sinitsin, 676
Monohydric Phenols, Application of the Simonis Reaction to, A. Robertson, 908
Monsters: The Mystery and Lore of, with Accounts of Some Giants, Dwarfs, and Prodigies, C. J. S. Thompson, 90
Moon: Eclipsed, The Spectrum of the, J. Dufay, 978; Total Eclipse of the: on April 2, 1931, Observation of the, M. Dehalu, 846; on Sept. 26, 550; Observation of the, of Sept. 26, 1931, made in Haute-Provence, E. Esclangon, 806
Moose-Wapiti Hybrid in Montana, An Alleged, 676
Mordellidæ, New (Coleoptera) in the Collections of the Zoological Museum of the Academy of Sciences, T. Sčegoleva-Barovskaja, 387
Moroccan Anti-Atlas, Presence of the Ordovician in the, A. Bigot and J. Dubois, 555
Moths, Melanism in, Inheritance of, A. W. McKenny Hughes, 496
Mouse, The Laboratory: its Origin, Heredity, and Culture, Dr. C. E. Keeler, 431
Mousterian (Levalloisian) Implements, Derived Early, in the Melt-water Gravels of the Coombe Rock Glaciation, J. P. T. Burchell, 909
Multiple Ionisation and Secondary X-Ray Absorption Edges, A. Sandstrom, 759
Muscovy Ducks at the Dairy Show, 791

Museums: Association, Annual Conference of the, 159; in Great Britain, Progress of, Sir Henry Miers, 330
Musical Sounds, Propagation of, Velocity of, R. de la Boulaye and G. Balme, 646
Mycobacterium cœliacum Gray and Thornton, The Systematic Position of, H. L. Jensen, 280
Mycorrhiza in Relation to Forestry, Dr. M. C. Rayner, 1011
Mysore Tribes and Castes, The, late H. V. Nanjundayya and Rao Bahadur L. K. Ananthakrishna Iyer. Vol. 3, 50

Naga Hills, Human Skulls and Bones from the, Dr. B. S. Guha and P. C. Basu, 762
Nagata's Comet, 1931 *b*, 229, 274, 912
Nansen's Last Journey, 319
Naphthalene Bisulphite Compounds, Researches on the, P. Lantz and G. Mingasson, 315
National: Expenditure, Committee on, Recommendations of the, 215; Ministries of Education, 732; Needs, 809; L. A. Fenn, 909; Needs (II.), 1053; Physical Laboratory: appeal for support of the Froude Laboratory and National Experimental Tank at the, 824; Inspection by the General Board, 74; Opening of new physics building, 14; new physics building at the, Dr. G. W. C. Kaye, 311; Radio Exhibition, The, 553
Nationalism and Science in China, 469, 1035
Native Administration: Anthropology and, 86; in Africa, 685
Natural Scenery, The Poetic Impression of, Dr. Vaughan Cornish, 656
Nature, One Touch of, a Literary Nature Study Reader for Boys and Girls, arranged by Dr. F. W. Tickner, 624
Nautilus, Progress of the, Sir Hubert Wilkins, 439
Naval Architects, Institution of: award of Scholarships, 161; award of the Elgar Scholarship to H. Lackenby and of the Earl of Durham prize to J. A. Price, 420; awards of the, to L. Redshaw and J. Irwin, 768
Neanthropic Man, Relation of, to the Ice Age, J. P. T. Burchell, 879
Nebulæ: Distant, The Velocities of, Hubble and Humason, 1007; Faint, A New Cluster of, Dr. W. Baade, 641
Necturus, Reactions of Dermal Melanophores in, to Heat and to Cold, Elsie H. Field, 163
Negative Images, Preparation of Fine Grain, by Development, A. Lumière and A. Seyewetz, 1086
Nematode Parasite of a Lucanid Beetle, A, J. R. Christie and B. G. Chitwood, 910
Nemertean, A New and Peculiar Marine, from the Australian Coast, Prof. W. J. Dakin and Mahalah G. C. Fordham, 796
Neon-Helium Bands, Dr. M. J. Druyvesteyn, 1076
Neujmin's Comet, 1913 III., Detection of, 587
New: Guinea, Expedition to, Dr. Margaret Mead, 823; South Wales, Mineralogy and Origin of the Natural Beach Sand Concentrate of, H. F. W. Whitworth, 316; Zealand, Science and Agriculture in, 981
Newcomen Society, Report for 1930–31, 932
ng and *np* Ultra-Violet Spectra Refracted by a Doubly Refracting Prism, The Separation of the, A. Brun, 1086
Nickel: -Chromium Alloys, Melting, in Hydrogen, Dr. C. J. Smithells, S. V. Williams, and E. J. Grimwood, 595; -Copper Alloys of High Elastic Limit, D. G. Jones, L. B. Pfeil, and W. T. Griffiths, 502; Ion in Solutions of its Chloride, The various Magnetic States of the, G. Foëx and Mlle. B. Kessler, 315
Nicotine, Excretion of, from the Aerial Parts of the Tobacco Plant, J. Chaze, 82
Nigeria, Anthropology in, P. Amaury Talbot, 285
Nitrate Deposits of California, L. F. Noble, 155
Nitrates: Mechanism of the Reduction of, M. P. Korsakova (3), 387; of Lime, Commercial, C. Matignon, 646
Nitrobenzene: and of Benzene, Melting Points of, Prof. I. Masson, 726; Change of Dielectric Polarisation of, with Temperature, Prof. M. Wolfke and Dr. J. Mazur, 584
Nitrogen: Compounds contained in Primary Tar, Hydrogenation of the, G. Roberti, 735; in Gases, The Direct Determination of, H. R. Ambler, 845; Pentoxide, The Thermal Decomposition of, J. H. Hodges and E. F. Linhorst, 83
Nitrogenous Excretion in Invertebrates, Prof. H. Delaunay, 306
Nitrosodithiocarbamates, L. Cambi and A. Cagnasso, 595
Nitrosyl Chloride, The Hydrolysis of, and of Nitrogen Peroxide by Caustic Potash, A. Perret and R. Perrot, 1086
Nobel Prize: for Chemistry, 1931, award of the, to Dr. C. Bosch and Dr. F. Bergius, 863; for Medicine for 1931, award of the, to Prof. O. Warburg, 789
Noise and its Measurement, Dr. G. W. C. Kaye, 251, 253
Non-ferrous: Metals and Alloys, Application of the Spectrograph to the Analysis of, H. W. Brownsdon and E. H. S. van Someren, 554, 802; Wires, The Drawing of, E. L. Francis and Prof. F. C. Thompson, 554
Nordsudetische Dyas: Die, eine stratigraphisch-palaographische Untersuchung, Prof. H. Scupin, 892
North: -East Coast: Institution of Engineers and Shipbuilders, Annual Report of the, 1070; institution of a Laing Memorial Lectureship, 670; Sea Earthquake, The, Rev. J. P. Rowland, 147; Floor, Deep Trench on the, Prof. J. W. Gregory, 37, 792; -West Australia, Rock-Paintings in, A. P. Elkin, 419; -West India, Eocene Mollusca of, L. R. Cox, 460
Northern Polytechnic, Dr. T. J. Drakeley appointed Principal of the, 124
Nottingham University College, Dr. H. L. Brose appointed Professor of Physics, 81
Nova Pictoris, The Distance of, Dr. Spencer Jones, 121
Novius Organum: Essays in a New Metaphysic, J. C. McKerrow, 562
Nuclear Moments, Prof. R. de L. Kronig and S. Frisch, 228
Nucleus, Quantum-Mechanical Models of a, R. H. Fowler, 453
Nudibranch, A Supposed Primitive Gill-less, Kikutaro Baba, 728
Nuer Customs and Folk-Lore, R. Huffman, 989
Nursery, Health and Education in the, Victoria E. M. Bennett and Dr. Susan Isaacs, 690
Nutrition: and Food Chemistry, B. S. Bronson, 856; *Journal of*, 306; Studies of, The Physique and Health of Two African Tribes, J. B. Orr and J. L. Gilks, 327

Occluded Gases, Influence of, on the Mechanical Properties of Metallurgical Products, L. Guillet, A. Roux, and J. Cournot, 978
Oceanic Bird Wanderers to Ceylon, W. E. Wait, 728
Œnothera, Chromosome Linkage in a Triploid, D. G. Catcheside, 460
Œnothera, Origin of Chromosome Linkage in, Prof. R. R. Gates and D. G. Catcheside, 637
Œuvres scientifiques, J. Janssen. Recueillies et publiées par H. Dehérain. Tomes 1 et 2, 239
"Of Composts shall the Muse disdain to Sing?" Prof. F. L. Engledow, 854
Official Statistics of the United Kingdom, Guide to Current, 266
Ogilvie, Sir Francis, The late, J. C. Smail, 118
Oil: and Petrol from Coal, Dr. C. H. Lander, 900; -Well Drilling, Deep, 93
Oils, Essential, Researches on, Prof. J. Read, 864
Oldoway: Bone Beds, Tanganyika Territory: Age of the, Dr. L. S. B. Leakey, A. T. Hopwood, and Prof. H. Reck, 724; New Yields from the, Dr. L. S. B. Leakey, A. T. Hopwood, and Prof. H. Reck, 1075; Further Discoveries in the, 995; Human Skeleton, The, J. Reid Moir, 797
Ondes et des corpuscles, La Synthèse des, K. K. Darrow, 629
Optical: Glass Manufacture, Recent Developments in, W. M. Hampton and W. N. Wheat, 926; Rotation and Atomic Dimension, D. H. Brauns, 876; Sensitisation, W. D. Bancroft, J. W. Ackerman, and Catharine Gallagher, 846

Orange and Allied Fruits, The Culture of the, Prof. H. C. Powell, 955
Oranges and Arsenates, P. v. d. R. Copeman, 120
Orchids of the South Maitland Coalfields, with description of a New *Dendrobium* from Bullahdelah, H. M. R. Rupp, 279
Ordnance Survey: Report for Year ending March 31, 1931, 867; The Small-Scale Maps of the, Brig. H. S. L. Winterbotham, 997
Ore-Minerals and the Microscope, 889
Organic: Acids in Plants, Nelson and Mottern, 415; and Mineral Compounds, Reactions between, R. de Fazi and A. Hemmeler, 43; Compounds, Downgrade Reactions of, Measurement of the Electricity Liberated during the, J. H. Wolfenden, 69; Gold Compounds, Kharasch and Isbell, 415; Oxides: Dissociable, a Dimethoxyrubrene, C. Dufraisse and R. Buret, 163; The Dissociable, C. Dufraisse and M. Badoche, 503; Syntheses, Vol. 11, 856
Orientator, The, Cooke, Troughton and Simms, Ltd., 102
Oriole, American, Song of an, A. H. Miller, 970
Orpheus: a History of Religions, S. Reinach. Revised and partly rewritten. Translated by Florence Simmonds, 628
Ørsted, Faraday and, Mrs. Kirstine Meyer, 337
Orthoptera Celebica Sarasiniana I., 671
Oscillators with very Short Waves, C. Gutton and G. Beauvais, 1013
Ostrich, A Fossil, from Transbaicalia, A. Tugarinov, 127
Ostwald-Luther Hand- und Hilfsbuch zur Ausfuhrung physiko-chemischer Messungen. Fünfte Auflage, 814
Overhead Transmission Cables, Insulation of, H. O. Austin, 416
Oxford University: the Savilian Chair of Astronomy, Dr. H. Dudden, 681; Dr. H. H. E. Craster elected Bodley's Librarian, 768; Prof. H. H. Plaskett appointed Savilian Professor of Astronomy, 930; gifts from Prof. J. M. Baldwin and the Royal Astronomical Society, 975
Oxidation: by Living Cells, Prof. J. B. S. Haldane, 175; -Reduction Potentials in Bacteriology, L. F. Hewitt, 73
Oxlip, Wild, Segregation of Floral Characters in the, Prof. F. E. Weiss, 305
Oxygen: and Everest: Dr. R. Greene, 893; N. E. Odell, 1037; Consumption, Oscillation in, during the Day and during the whole Life of Invertebrates, K. Michael, 1013; Elementary, An Experimental Study on the Estimation of Traces of, F. Novotny and F. Toul, 1013; Hydrogen and, Combination of, W. L. Garstang and H. L. Hinshelwood, 1044; The Absorption Spectrum of, at High Temperatures, D. Malan, 386
Oyster, Sex-change in the, Prof. J. H. Orton and C. Amirthalingam, 273
Ozone: Photosensitised Decomposition of, by Bromine, J. W. T. Spinks, 548; Ultra-Violet Spectrum of, O. R. Wulf and E. H. Melvin, 763

Pacific Science Congress, the fourth, 1033
Paget, Stephen, Memorial Lecture, Dr. H. H. Dale, 499
Palæolithic: Flint Implements, J. Reid Moir, 767; Man: and the Nile-Faiyum Divide: a Study of the Region during Pliocene and Pleistocene Times, Dr. K. S. Sandford and Dr. W. J. Arkell, 287; in Egypt, 287
Palæontology: Outlines of, Prof. H. H. Swinnerton. Second edition, 173; The Evidence of, with regard to Evolution, Prof. A. E. Trueman, 990
Paläoklimatologie, Dr. F. Kerner-Marilaun, 1025
Palo Alto Tree, The, Miss A. I. Weymouth, 904
Pancreatic Juice, Number and Nature of the Proteolytic Ferments of the, Mlle. E. Lebreton and F. Mocoroa, 199
Pancreatin, Action of, upon different Types of Wool, C. Fromageot and A. Porcherel, 1013
Paper Making: Dr. E. F. Armstrong, 949; The Digestion of Grasses and Bamboo for, W. Raitt, 949
Paracentrotus lividus, Action of Sea Water, in which Carotene has remained, on the Experimental Development of, J. A. Thomas, 978
Paraffin Oil, The Oxidation of, G. Arditti, 882
'Paragutta', A. R. Kemp, 218
Paramagnetic Salts in Aqueous Solutions, The Magnetic Double Refraction of, C. Haenny, 1086
Parasitology, Human, Introduction to, Prof. A. C. Chandler. Fourth edition, 323
Paris: Observatory, Report for 1930, 1081; University, conferment of Honorary Doctorates on Prof. W. B. Cannon and Prof. H. F. Osborn, 936
Parsons, Sir Charles, The Life and Work of the late, Sir Alfred Ewing, 932
Parthénogénèse, La, Prof. A. Vandel, 941
Parthenogenesis, Problems in, Prof. A. D. Peacock, 941
Patent: Litigation, The Cost of, W. H. Ballantyne and H. A. Gill, 790; System, British; Reform of the, 165
Paths, Systems of, A Characteristic Property of, C. H. Rowe, 1086
Peabody Museums of Natural History, 'Special Guides' to the, 113
Peat Fuel Power Station in Russia, A, F. C. Wigham, 406
Peking Man and Stone Implements, 823
Penetrating: Corpuscular Rays coming from Inclined Directions, Measurements on the Absorption of the, Prof. B. Rossi, 408; Rays, Origin of, Prof. Gianfranceschi, 581
Peppermint Oil, Evaluation of the Menthone Content of, Prof. J. Reilly, N. Noonan, and P. J. Drumm, 845
Pereira Medal of the Pharmaceutical Society, Presentation of the, to H. G. Rolfe, 667
Peridote, The Apparent Dispersion of the Optical Axes in, and the Measurement of $2V$, A. Brun, 1086
Periodic Physico-Chemical Phenomena, Dr. E. S. Hedges, 398
Periodicals, The Subject Index to, 1929, 562
Peroxides in the Gases from Internal Combustion Motors, Dumanois, Mondain-Monval, and Quanquin, 43
Perseid Meteors observed in America, 550
Peru: Balsam, The Dry Distillation of, J. Dupont and J. J. Guerlain, 646; from the Air, Lieut. G. R. Johnson. With Text and Notes by R. R. Platt, 172
Petrol-Alcohol-Benzene Mixtures, C. Baron, C. Boulanger, and R. Le Grain, 163
Petunias, Tetraploid and Triploid, Dr. D. Kostoff and J. Kendall, 227
Pflanzenmikrochemie: ein Hilfsbuch beim mikrochemischen Studium pflanzlicher Objekte, Dr. A. Tunmann. Zweite Auflage bearbeitet von Prof. L. Rosenthaler, 953
Pharmacy, School of, of the Pharmaceutical Society, Address to Students of the, Prof. G. E. Gask, 667
Phenological Observations in the British Isles from Dec. 1929 to Nov. 1930, J. E. Clark, I. D. Margary, R. Marshall, Capt. C. J. P. Cave, and L. C. W. Bonacina, 917
Philippines, The Tectites of the, A. Lacroix, 554
Philosophy, A Defence of, Prof. R. B. Perry, 964
Phosphate of Trivalent Manganese and of Aluminium, A. Yakimach, 315
Phosphorescence of the Sea, 843
Phosphoric Acid, The Electrometric Titration of, A. Sanfourche, 82
Phosphorus, Green Flame of, Band Spectrum of the, Dr. E. B. Ludlam, 271
Photoconductance in the Photovoltaic Effect, Rôle of the Phenomena of, R. Audubert and J. Roulleau, 555
Photoelectric: Cells: Gas-filled, Accuracy obtainable with, Dr. W. R. G. Atkins, 550; New Facts ascertainable by means of ordinary, Q. Majorana, 734; Effect, The, R. H. Fowler, 415; Investigations, New, Q. Majorana, 647; Relay, A, Dr. L. Bergmann, 677
Photoelectrons and Negative Ions, Prof. E. M. Wellish, 547; Dr. J. L. Hamshere, 871
Photography, International Congress of, 543
Photon: Evidence for the Spin of the, from Light-Scattering, Sir C. V. Raman and S. Bhagavantam, 114; Dr. G. Placzek, 410; The Spin of the, Prof. M. N. Saha and Y. Bhargava, 870
Photovoltaic Cells, The Rôle of Water in, R. Audubert, 466

Physical Metallurgy Laboratory Manual, Dr. N. E. Woldman, 779
Physico-Chemical Phenomena, The Lower Limit of, Ç. E. Guye, 279
Physics: A Survey of, Prof. F. A. Saunders, 628; Critique of, L. L. Whyte, 964; for College Students, A Survey of, Prof. F. A. Saunders, 134; General, Prof. W. S. Franklin and Prof. G. E. Grantham, 134; in Sound Recording, A. Whitaker, 933; Institute of, Dr. H. R. Lang appointed Secretary of the, and Editor of the *Journal of Scientific Instruments*, 1036; Intermediate, Dr. R. A. Houston, 134; International Union of, Brussels Meeting, 1931, 485; Theoretical, Lectures on, delivered at the University of Leiden, Prof. H. A. Lorentz. Translation by Dr. L. Silberstein and A. P. H. Trivelli. Vol. 3: Maxwell's Theory, Edited by Dr. H. Bremekamp; The Principle of Relativity for Uniform Translations, Edited by Dr. A. D. Fokker, 959
Physiology: General, An Elementary Course in, Part 1: Principles and Theory, Prof. G. W. Scarth. Part 2: Laboratory Exercises, Prof. F. E. Lloyd and Prof. G. W. Scarth, 563; Human Experimental, An Introduction to, Dr. F. W. Lamb, 475
Physique mathématique, Les méthodes de solution approchée des problèmes de la, Prof. N. Kryloff, 963
Phytoplankton from South African Pans and Vleis, F. Rich, 316
Pierce, Lorne, Medal of the Royal Society of Canada, award of the, to Adjutor Rivard, 275
Piezoelectric Quartz Frequency Meter with Synchronous Modulation, A, B. Decoux, 386
Pigafetta, New Gyro-stabiliser for the, 934
Pigeon, Homing, Remarkable Flight of a, 668
Pigment Migration in the Chromatophores of Crustaceans, Control of, E. B. Perkins and T. Snook, 423
Pigmy Right Whale (*Neobalæna*), The, H. M. Hale, 910
Pinnipedia from the Neogene Deposits in Western Siberia, Remains of a Primitive Representative of, J. Orlov, 503
Pit-Dwellings at Kiatuthlanna, Eastern Arizona, F. H. H. Roberts, Jr., 154
Pittsburgh, Air Pollution at, H. B. Meller, 307
Pituitrin: Injected in the Ventricle, The Counteractive Effect of Tribromethanol (Avertin) on the Stimulating Response to, H. Cushing, 422; introduced into the Ventricle, Method of Action of, H. Cushing, 422
Pivots and Jewels, V. Stott, 273
Planet, New Minor, An interesting, 641
Planetary System, Birth of the, Theories of the, Prof. W. de Sitter, 972
Planets, Minor, The numbering of, 800
Plant: Biochemistry: Prof. A. R. Ling, 621; The Principles of, Hon. Mrs. Muriel Wheldale Onslow, Part 1, 621; Breeding in Germany, Dr. Baur, 975; Contents, Adobe Brick Analysis for, G. W. Hendry, 1006; Genetics: Abstracts of Papers on, 65; for Herbage Plants, Imperial Bureau of, *Bulletin* of the, 407; Life through the Ages: a Geological and Botanical Retrospect, Prof. A. C. Seward, 559; Patent, the first, granted by the U.S. Patent Office, 994; Physiology: with reference to the Green Plant, Prof. E. C. Miller, 952; Processes, Physical Attributes in, 240; Virus Diseases: Dr. J. Henderson Smith, 635; Insect Relations of, Dr. Kenneth Smith, 915
Plants: and Geology, 559; Exploring for, D. Fairchild, 52; Life Movements in, edited by Sir Jagadis Chunder Bose, 240; Mortality among, and its bearing on Natural Selection, R. Wetherall, 23; The Phosphorus Compounds of, E. Mnich (6), 279
Platinum, Influence of the Field on the Magnetic States of, Mlle. Paule Collet and G. Foex, 82
Pleistocene Period, Duration of the, G. F. Kay, 586
Pleurodictyum megastomum, The Development of the Tabulate Coral, R. B. Withers, 127
Pluto, Orbit and Mass of, Dr. E. C. Bower, 1047
Poincaré, Henri, Annales de l'Institut, Fasc. 2, Vol. 1, 243; recueil de conférences et mémoires de calcul des probabilités et physique théorique. Vol. 1, fasc. 3, 657
Polar: *Record*, The, July, 581; Year 1932–1933, arrangements for the, Dr. G. C. Simpson, 793
Polarising Microscope, Use of the, in the Determination of Organic Substances, E. Galopin, 734
Polarity and Vapour Pressure, Dr. A. R. Martin, 456
Polonium: A New Gaseous Compound of, Mme. Irène Curie and M. Lecoin, 199; A New Reaction of, M. Haissinsky, 315; in Tartaric Acid Solution, The Electrochemical and Chemical Behaviour of, M. Haissinsky, 199; The Centrifugation of Solutions of, in the Presence of Various Electrolytes, Mlles. C. Chamié and A. Korvezee, 82; The Separation of, and of Protactinium fixed on Tantalum Oxide, F. Reymond and Tcheng da tchang, 386
Polyhedra, Embryology and the Theory of, Prof. D'Arcy W. Thompson, 31
Population: and Production, Prof. E. Cannan, 534, 658; Density and the Optimum for Life, relation between the, and of this to the Sex Ratio, in some Invertebrates, K. Michal, 1013; Problems, 10; Some Problems of, Sir Leonard Hill, 488; Theories of, from Raleigh to Arthur Young: Lectures delivered in the Galtonian Laboratory, University of London, under the Newmarch Foundation, February 11 to March 18, 1929, with two additional Lectures and with References to Authorities, Dr. J. Bonar, 940
Porcelain, A New, without Silica, based on Pure Fluorspar, R. Damiens, 82
Porphyro-quartz of Samshvildo, The Regular Formation of Twins in, G. Laemmlein, 387
Position: in High Latitudes, Determination of, with Particular Reference to Aircraft Observation, C. J. Stewart, 212; Physiological Perception of, 815
Positivismus und reale Aussenwelt, Prof. Max Planck, 289
Posterior: Lobe Extract (Pituitrin), Similarity in the response to, and to Pilocarpine when injected into the Cerebral Ventricles, H. Cushing, 280; Pituitary Extract (Pituitrin), Reaction to, when introduced into the Cerebral Ventricles, H. Cushing, 280
Potassium: β-Radiation of, A Hard Component of the, D. Bocciarelli, 374; Permanganate, Influence of Fluoride Ions upon the Reduction of, W. Pugh, 682; Salts, The Physiological Characteristics of, D. Prianischnikov and V. V. Butkevitch, 163
Potato: Plants affected with Certain Virus Diseases, Cytological Studies of, Phyllis Clinch, 198; Productivity of the, Influence of a Period in the Mountains on the, J. Costantin, P. Lebard, and J. Magrou, 1086
Potatoes, Healthy and Leaf Roll, Respiration of, Dr. T. Whitehead, 967
Potential, The Theory of, R. Wavre (i), 682
Potentilla, *Chrysanthemum* and, Chromosome Multiples in, N. Shimotomai, 72
Potters' Stamps on Terra Sigillata "Samian Ware", Index of, Dr. F. Oswald. With a Supplement, 951
Pottery with Flint Implements of Upper Palæolithic Facies from Swanscombe, Kent, J. P. T. Burchell, 548
Poultry, Size-Inheritance in, W. T. Waters, 1005
Power: Sir Alfred Ewing, 567; Engineering, Origins of, H. P. Vowles, 800
Praseodymium and Thallous Sulphates, F. Zambonini and S. Restaino, 1014
Pre: -Cambrian Tillite in South-West Africa, Dr. T. W. Gevers, 191; -Chellean Age in the Gravels of Stanstead, Upper Caterham, apparently Site and New Culture of, L. MacLellan Mann, 144
Precipitation, Periodic, in the Absence of Colloids, Prof. J. W. McBain, 1042
Pregl's Method for Determining Nitrogen, Modification of, J. J. Rutgers, 421
Prehistoric: Colonists of Yorkshire, The, and their Economics, Prof. V. Gordon Childe, 776; Society of East Anglia, 879
Prehistory: An International Congress of, 389; Association and Chronology in, A. J. H. Goodwin, 801
Prejudice: A Plea for, 473; in Modern Civilization (Prejudice and Politics), The Place of, Sir Arthur Keith, 473
Prickly-Pear, Control of, by the Cochineal Insect, C. T. Jacob, 117; T. V. Ramakrishna Ayyar, 837; W. B. Alexander, 226

Priestley: and Lavoisier, Sir Philip Hartog, 797; as a Pioneer, 464; Joseph: A Life of, Anne Holt, 625; and his place in the History of Science, Sir Philip Hartog, 464
Primates, Cerebral Evolution of the, with special reference to the Hominidæ, Prof. C. Fraipont, 61
Probabilités et statistiques, Dr. R. de Montessus de Ballore, 286
Probability Theorems connected with the discovery of Variable Stars by a Photographic Method, B. Gerasimovic, 682
Production, Population and, Prof. E. Cannan, 534, 658
Prophylaxis, Experiments in, Sir Flinders Petrie, 35
Protactinium, Purification of the, fixed on Tantalum Oxide, Tcheng Datchang, 466
Proteins: Hydration of, The Volume Contraction produced by the, C. Marie and N. Marinesco, 978; in their Native State, Molecular Weights of the, Prof. The Svedberg, 999
Proton: On the Mass of the, Sir Arthur Eddington, 1049; Waves, The Diffraction of, Y. Sugiura, 1006
Protons, Collision Properties of, C. Ramsauer, R. Kollath, and D. Lilienthal, 911
Protoplasm: Extensibility of, Prof. W. Seifriz and Janet Plowe, 1045; The Permeability of, to Water, B. Huber, 497
Protozoölogy, Problems and Methods of Research in, J. Andrews and others. Edited by Prof. R. Hegner and J. Andrews, 395
Psychology: and Organised Religion, Prof. R. Pearl; J. R. Miner, 1047; Integrative, a Study of Unit Response, Dr. W. M. Marston and C. D. King and Elizabeth H. Marston, 1025
Psycho: -neurotics, The Concentric Method in the Diagnosis of, Prof. M. Laignel-Lavastine, 690; -physical Law, The Fundamental, A. Tsvetkov, 503
Public Health: Pioneers of, the Story of some Benefactors of the Human Race, M. E. M. Walker, 6
Puccinia: *graminis tritici*, Effect of Light on Urediniospores of Black Stem Rust of Wheat, W. A. R. Dillon Weston, 67; *pygmæa* Erikss. on *Berberis*, An Æcidium of, W. Tranzschel, 467
Pueblo and related Indian Races, Skulls of the, Dr. A. Hrdlička, 1079
Pulp-Wood Market in the United States, The, 313
Purkinje's Phenomenon, Nature of, P. Rossier, 235
Pyrethrins in the Pyrethrum Flower, Distribution of the, L. and J. Deshusses, 126
Pyruvic Acid in Lactic Fermentation, Formation of, S. P. Kostychev, V. Gvaladze, and P. S. Eliasberg, 127

Qualitative: Analysis by 'Spot' Tests, 987; Analyse mit Hilfe von Tupfelreaktionen: theoretische Grundlagen und praktische Ausfuhrung, Dr. F. Feigl, 987
Quantitative Analysis, Textbook of, Prof. W. T. Hall, 323
Quantum: Mechanical Motion of Free Electrons in Electromagnetic Fields, E. H. Kennard, 83; Theory, An Introduction to, Dr. G. Temple, 960
Quartz: Anomalous Variation of the Electrical Conductivity of, with Temperature at the Transformation Point, Prof. H. Saegusa and S. Shimizu, 835; Crystallised, and Fused Quartz, Comparison of the Magnetic Rotations of, A. Cotton, 81; Resonators and Oscillators, P. Vigoureux, 961
Quaternary Ice Margins (North Sea), Prof. J. K. Charlesworth, 498
Quebec, Pre-Cambrian Rocks of, H. C. Cooke, W. F. James, and J. B. Mawdsley, 1006
Quekett Microscopical Club, Recollections of the, J. M. Offord, 29
Quinine Sulphate, The Radiation accompanying the Hydration of, M. Curie and M. Prost, 386

Rabbit: Breeding, The Scientific Aspects of, J. N. Pickard and Prof. F. A. E. Crew, 512; Industry, Science in the, 512
Rabbits, Some Diseases of, 219
Race and Progress, Prof. F. Boas, 557
Racemic Aldehydes, Optical Resolution of, (2), M. Betti and P. Pratesi, 1014
Racial Prejudice, 557
Radicals, Free Neutral, Fluorescence and, A Connexion between, Dr. W. A. Waters, 905
Radiation: and Life, Dr. W. R. G. Atkins, 199; Matter and, Prof. F. G. Donnan, 290; Ultra-Violet, Measurement of, A. F. Dufton and H. E. Beckett, 223
Radiations from Radioactive Substances, Sir Ernest Rutherford [Lord Rutherford], Dr. J. Chadwick, and Dr. C. D. Ellis, 3
Radioactive Constants, The, 1006
Radioactivity: and Earth Movements, Prof. A. Holmes, 419, 496; and the Atomic Nucleus, Prof. A. H. Compton, 3; of the Atmosphere in Czechoslovakia, 903
Radio: Beacon Stations of the Rotating Type, 252; Broadcasting Stations in Europe, Increase of, 903; Communication, Modern, J. H. Reyner. Third edition, 1057; -electric Waves, The Propagation of, R. Jouaust and N. Stoyko, 82; -elements and Isotopes: Chemical Forces and Optical Properties of Substances, Prof. K. Fajans, 948; Frequency Measurements, The Theory and Practice of, E. B. Moullin. Second edition, 1057; Observations during a Solar Eclipse, Dr. M. A. F. Barnett, 381; Research: Board, Report of the, for the year ended 31st Dec. 1930, 861; in Great Britain, 861; in the British Empire, R. A. Watson Watt and O. F. Brown, 755; Signal across the Atlantic, Thirtieth Anniversary of the First, 1031; Signals passing through High Latitudes, Abnormality of, S. Namba, 1044; -telegraphy, Second Thoughts on, 1057; -telephone System, Demonstration of a, in Italy, 902; -therapy, Ultra-Violet, Dr. W. K. Russell, 953
Radium: Commission, Second Annual Report of the, 803; Concentration of, by Plants, V. Vernadskii, 127; in Hawaiian Lavas, C. S. Piggot, 840
Raffety Bands, The, and the Spectra of Comets, F. Baldet, 234
Railway Electrification: in India, 406; in Italy, 146
Rainfall: as Carbohydrates, Conservation of, Prof. W. A. Osborne, 378; in a given place, Usefulness of long Periods of Observation of the, E. Mathias, 918; Eighty Years', at North Craig Reservoir, Kilmarnock, W. Dunbar, 917
Raman: Band in Water, Structure of the, S. Rafałowski; Dr. G. Bolla, 546; Bands in Water, S. Rafałowski, 978; Effect: Enlargement of Diffused Lines without change of Frequency in the, Mlle. M. Ney, 126; Prof. K. W. F. Kohlrausch, 155; in Chemistry, The, R. Lespieau, M. Bourguel, and R. L. Wakeman, 503; Lines: due to Co-ordination Bond, Prof. D. M. Bose and S. Datta, 725; in Liquids, Fine Structure of, Dr. A. Langseth, 225; Scattering: in Gases, Intensity of, S. Bhagavantam, 272; Polarisation of, by Hydrogen Gas, S. Bhagavantam, 70; Spectra: Effect of Pressure on, S. Bhagavantam, 188; in the Ultra-violet, The Monochromatic Stimulation of, Horia Hulubei and Mlle. Yvette Cauchois, 315; of Benzene and Toluene, L. E. Howlett, 796; of Crystals, Lines of Large Frequency Shift in the, Prof. R. Tomaschek, 495; of Liquid Mixtures, P. Krishnamurti, 639; Spectrum: and Chemical Constitution of certain Chloroethylenes, G. B. Bonino and L. Brull, 595; of CO_2, Rotational, W. V. Houston and C. M. Lewis, 280; of Dichlorobromomethane, G. B. Bonino and L. Brüll, 1051; of Hydrogenated Derivatives of Naphthalene, G. B. Bonino and P. Cella, 1051
Ramsay: Fellowships, award of, 313; Memorial Laboratory of Chemical Engineering at University College: opening of the, by Prince George, 932; The, 1046
Rare: Earths, Sulphates of the, A Physico-chemical Study of the, Prof. B. Brauner and E. Švagr, 1013; Gas Spectra, Intensity Anomalies in, E. Rasmussen and H. Swenson, 188
Rat, The Local Effects in the, due to Electric Fields of very High Frequency, J. Saidman, J. Meyer, and R. Cahen, 387
Rationalisation, The International Discussion Conference and, 405
Rationalization, Dr. J. A. Bowie, 92
Rats and Mice as Enemies of Mankind, M. A. C. Hinton. Third edition, 1036
Rayons de courbure des surfaces sphériques employées en optique, La mesure des, A. Arnulf, 323

Red Algæ, Resistance Experiments on, A. Zeller, 467
Reflector, Another large, in America, 381
Registrar-General's Statistical Review, 1930; Tables, Part 2, Civil, 997
Relativistic Opacity Coefficient, The, R. C. Majumdar and D. S. Kothari, 908
Religion, Organised, Psychology and, Prof. R. Pearl; J. R. Miner, 1047
Repton School Science Society, Conversazione of the, 15
Research in Industry and Rationalisation, A. Y. Enström, 122
Resonator, Bottle-Pipe, The, A. E. Bate, 270
Reticulo-endothelial Blocking, Variations of the Blood Serum Albumins under the Influence of, A. H. Du Bois, 279
Reversible Coagulation in Living Tissue, W. D. Bancroft and G. H. Richter, (3), 423; (4), 846; 1014

REVIEWS AND SHORT REVIEWS.

Agriculture, Forestry, and Horticulture:

Gill (T.), Tropical Forests of the Caribbean, 1059

Royal: Anthropological Institute, Foundation of a Gold Medal by, Dr. H. S. Wellcome, 904; College of Science, Scientific Journal of the, Vol. 1, 627; College of Surgeons of England, Lord Moynihan re-elected president of the, 101; Commission on the Civil Service, The, 201; Institution: Rumford and the, a Retrospect, T. E. James, 476; Meteorological Society, Phenological Report for 1930, 633; Microscopical Society, Prof. V. Grégoire and Prof. O. Rosenberg elected Honorary Fellows, 834; Photographic Society, Exhibition of the, 543, 822; Society: Prof. C. Fabry, Dr. E. de Margerie, and Prof. H. Wieland elected Foreign Members of the, 64; Anniversary Meeting of the, presentation of Medals, 973; award of Medals, 821; recommendations for election as Officers and Council of the, 864; award of Royal Medals to Sir Richard Glazebrook and Prof. W. H. Lang, 973; award of the Copley Medal to Sir Arthur Schuster, 973; award of the Davy Medal to Prof. A. Lapworth, 973; award of the Hughes Medal to Prof. W. L. Bragg, 974; award of the Sylvester Medal to Prof. E. T. Whittaker, 974; of Canada: Annual Meeting in Toronto, 275; Sir Robert Falconer elected President of the, 276;

of Edinburgh, election of Officers, 793; for the Protection of Birds, Report of the, 633; Swedish Academy of Science, Sir Sidney Harmer elected a Foreign Member of the, 723
Rubber: Artificial, E. I. du Pont de Nemours, 1044; Research Institute of Malaya, Report of the, 880
Rubidium Spectrum, Hyperfine Structure in the, D. A. Jackson, 34
Ruled Surfaces, The Theory of, W. L. Edge, 856
Rumford and the Royal Institution: a Retrospect, T. E. James, 476
Rural Electrification, E. W. Dickinson and H. W. Grimmitt, 902
Russia: and the U.S.S.R., Faraday and Electrical Science in, W. T. Mitkewich, 359; Industrialisation in, Wigham, 544
Russulas, The Spore Ornamentation of the, R. Crawshay, 891
Rust Diseases of Cereal Crops, Sir R. H. Biffen, 728
Ruwenzori, Uganda, Petrology of the Volcanic Fields east and south-east of, Prof. A. Holmes and H. F. Harwood, 977

Sacred Bull, Cult of the, in Ancient Egypt, O. H. Myers, 119
Safety: in Mines Research Board, Annual Report, 698; Work in Chemical Industries, 1
Sahara, Magnetic and Electrical Observations in the, C. Le Camus and F. de Saint-Just, 882
St. Andrews University: Dr. F. L. Arnot appointed Lecturer in Natural Philosophy, and Dr. G. L. Montgomery Lecturer in Clinical Pathology, 81; Fire Outbreak at, 822; Genl. J. C. Smuts elected Rector, 916
St. Kilda, Change of owner of, 182
Sâl, Seeds and Seedlings of, H. G. Champion and B. D. Pant, 1080
Salix, The Biochemical Study of the genus, C. Charaux and J. Rabaté, 199
Salt Hydrate, Dissociation of a, Function of Water Vapour in the, B. Topley and M. L. Smith, 302
Salters' Institute, award of fellowships of the, 313
Salts: Complex, Absorption Spectra of, Dr. R. Samuel, 729; Dehydration of, Dr. M. Copisarow, 838; of the Iron Group, Gyromagnetic Effect for, W. Sucksmith, 640
Saluda Hydro-Electric Station near Columbia, Completion of the, 330
Santonine, The Mechanism of the Antiglycosuric Action of, A. Leulier and Mme. Andrée Roche, 422
Saturated Hydrocarbons in the Gaseous State, The Thermal Conductivities of, W. B. Mann and B. G. Dickens, 881
Saturn's Ring, The Mass of, H. Slouka, 972
Save the Children International Union of Geneva, Section of Preventive Pædiatrics, Congress of the, 544
Scheele: Carl Wilhelm, The Collected Papers of, Translated by Dr. L. Dobbin, 1023; The Works of, 1023
Schistosomiasis (Bilharziasis), Zoological, Clinical, and Prophylactic, The Bibliography of, Prof. Mohamed Bey Khalil, 65
Schlammanalyse, Die, Dr. H. Gessner, 1061
School Life, January, 197
Schwarzschild Relation, The Validity of the, as applied to the Use of the Logarithmic Sector, F. Twyman and A. Harvey, 770
Sciara, Differences between Chromosome Groups of Soma and Germ-line in, C. W. Metz and M. Louise Schmuck, 423
Science: Advancement of, London and the, 687; Advancing, being Personal Reminiscences of the British Association in the Nineteenth Century, Sir Oliver Lodge, 982; and Agriculture in New Zealand, 981; and Curative Medicine (Stephen Paget Memorial Lecture), Dr. H. H. Dale, 499; and Humanity, 505; and Industry, Creative, 317; and Service, 921; and Technology, The International Congress of the History of, Dr. T. Greenwood, 77; at a New Angle, 562; at the Cross Roads. Papers presented to the International Congress of the History of Science and Technology . . . by the Delegates of the U.S.S.R., 170; Bibliography of, Classification for, Dr. S. C. Bradford, 268; in the City of London, Engr.-Capt. E. C. Smith, 515; Man of, The Faith of a, Sir Daniel Hall, 1069; Museum: A New Children's Gallery at the, 994; Sir Richard Glazebrook appointed Chairman of the Advisory Council of the, 184; National Teaching of, Problems in the (Pedler Lecture), Prof. I. Masson, 753; Post-Primary, W. F. F. Shearcroft. Book 1: First Year's Course, 960; The Beginnings of, Dr. C. Singer, 7; The Recorded Data of, 662; The Social Function of, Prof. C. H. Desch, 824
Scientific: Abstracting Services, Organisation of, A. A. Eldridge, 1004; and Industrial Research, Department of, Dr. F. S. Sinnatt appointed Director of Fuel Research, 1072; and Technical Books, Recent: July 25, v; Aug. 22, v; Oct. 31, v; Nov. 28, v; Dec. 26, v; Management Problems, 1008; Men as Administrators, 237; Research and Invention, The Value of, Prince of Wales, 60; World-Picture of To-day, The, Genl. J. C. Smuts, 521
Scorodite from Kiura Mine, Bungo, Kiushiu, Japan, T. Ito and T. Shiga, 977
Scottish Marine Fauna, Studies in the, R. Elmhirst, 42
Scylliorhinus Canicula, The Physiological Nature of the Diastase, secreted by the Eclosion Gland in, Ouang Te Yio, 846
Sea: -Angling Fishes of the Cape (South Africa), C. L. Biden, 209; -elephant, A, at Cape Point, 634; -lion Census, A, P. Bonnet, 640; Phosphorescence of the, 843; Stars, South American, W. K. Fisher, 154; -urchin, Larvæ of the, Influence of Metallic Silver on the Calcification of the, G. Bohn and Mme. Anna Drzewina, 806; Water, Irradiation of, by Ultra-Violet Rays, etc., L. Sanzo and F. Pirrone, 806
Seed Analysis, Commercial, British Association of, Annual Meeting of the, 265
Seedlings in some Grasses, Latency of, H. G. Chippindale, 1075
Seeds, Damaged, Germination of, 307
Seismological: Committee of the British Association, Report of the, 580; Messages, a Provisional Code for, 994; Stations, New, 181
Seminal Vesicle, Regulation of the Secretory Activity of the, H. Burchardt, 468
Serpent Worship, W. D. Hambly, 1043
Serum Albumin, Temperature Stability and Denaturation of, Dr. K. O. Pedersen, 150
Service, Science and, 921
Sex Rites and Customs: A Bibliography of, an Annotated Record of Books, Articles, and Illustrations in all Languages, R. Goodland, 892
Sheep, A Naked, E. T. Popova-Wassina, 866
Sheffield University: appointment of B. H. Bentley as Professor of Botany, of Dr. R. N. Rudmose Brown as Professor of Geography, of L. E. S. Eastham as Professor of Zoology, of Dr. J. Florey as Professor of Pathology, and Dr. J. W. Edington as Professor of Bacteriology, 1048; Prof. J. H. Andrew appointed Professor of Metallurgy, 975
Shells, Industrial, of the Philippines, F. Talavera and L. A. Faustino, 676
Shipping, Engineering, and Machinery Exhibition, The, 488
Ship-waves, Rhythmic Breaking of, Prof. Kerr Grant, 838
Shoalhaven River Valley, Physiography of the, F. A. Craft (1), 279; (2), (3), 387
Short Wave Reception and Ultra-Radiation, Dr. W. M. H. Schulze, 837
Shoshonean Linguistics, Dr. E. Sapir, 379
Shrikes, The Impaling Instinct of, A. H. Miller, 1005
Siam: Nature and Industry, 209
Siderolite from Bencubbin, Western Australia, A New, E. S. Simpson and D. G. Murray, 977
Sigma Scorpii, B. H. Dawson, 1081
Silica: remaining after attacking Leucite with Acids, Certain Properties of the, G. A. Blanc, 647; Vessels, Influence of Hydrogen on Chemical Changes in, Prof. M. W. Travers, L. E. Hockin, and T. J. P. Pearce, 66
Silkworms, Starch Digestion in, Osamu Shinoda, 497
Silver: Bivalent, Paramagnetism of, Prof. G. T. Morgan and Dr. S. Sugden, 31; and Mercury, Alloys of, Constitution of the, Dr. A. J. Murphy, 554, 1082

Simonis Reaction, Application of the, to Monohydric Phenols, A. Robertson, 908
Slate, X-Ray Analysis of, H. V. Anderson, and K. C. Chesley, 1043
Sleep, Bodily Position in Restful, Dr. H. M. Johnson, 190
Slide Rule: A Manual of the, its History, Principle, and Operation. Second edition, 563
Smallpox Prevention, Review of certain Aspects of, 148
Smekal-Raman-Effekt, Der, Prof. K. W. F. Kohlrausch, 1026
Smithsonian Institution: Explorations and Field-work, 1930, 147
Smoke Abatement Handbook, 1034
Smooth Surfaces, On the Contact of, S. H. Bastow and F. P. Bowden, 881
Snakes: Attraction of, to Dead Ones, 329; Insectivorous, Prof. F. J. Meggitt, 413
Soap and Detergent Industry, The Modern, Dr. G. Martin. Second edition. 2 vols., 625
Social Economics, Industrial and, 773
Société: française des Électriciens, title of Honorary Member of the, conferred on P. F. Rowell, 834; Zoologique de France, Sir Sidney F. Harmer elected an Honorary Member of the, 29
Society Islands, Class Distinction in the, Dr. E. S. C. Handy, 459
Soda, The Reduction of, P. Villard, 978
Soies artificielles et matières plastiques, R. Gabillion, 855
Soil: *Bulletin*, The, 298; Classification, L. L. Lee, 677; Science, The Aims and Objects of, Prof. I. de V. Malherbe, 801; The Physical Properties of the, Dr. B. A. Keen, 391
Soils, The Interchange of, L. I. Jones, 668
Solar: Corona, Forms of the, and their Origin, Dr. W. J. S. Lockyer, 784; Radiations, Influence of the, on the Temperature of the Bodies of Insects, J. D. Strelnikov, 125; System, The Origin of the, Sir James Jeans, 432
Solid State, The Architecture of the, Prof. W. L. Bragg (Kelvin Lecture), 210, 248
Solution, Association Theory of, and Inadequacy of Dissociation Theory, Jitendra Nath Rakshit, Rai Sheheb, 852
Solutions, Constitution of, deduced from Absorption Measurements, P. Vaillant, 918
Solvents, Dr. T. H. Durrans, 958
Sonora, Mexico, Land Birds of, A. J. van Rossem, 190
Soral (Canton of Geneva), The Phreatic Sheet of, E. Joukowsky, 235
Sound: in Tubes: Velocity of, Ultrasonic Method, G. S. Field, 117; Production, The Effective Mass of Flexible Discs and Conical Diaphragms used for, Dr. N. W. McLachlan, 733
Sounds, Isolated, Articulation of, C. E. Parmenter, S. N. Trevino, and C. A. Bevans, 380
South: Africa: medal of the South African Association, award of the, to Prof. H. B. Fantham, 29; New Game Reserves in, Prof. H. B. Fantham, 992; African: Association: 1932, election of Prof. P. J. du Toit as President, 802; Grahamstown Meeting. Presentation of South Africa Medal and grant to Prof. H. B. Fantham, 801; Museum, Progress of the, 265; Tribe, Ethnological Survey of a, 614; Australia, The Rift Valleys of, Dr. C. Fenner, 155; London: Botanical Institute, Twenty-first Anniversary of the, 697; Entomological and Natural History Society, *Proceedings* for 1931–32, 635; Russian Steppe Graves, Prof. V. Gordon Childe, 190
Southampton, University College of: Wing Comdr. T. R. Cave-Browne-Cave appointed Professor of Engineering and H. Leech Experimental Engineer, 681; S. Weintroub appointed an Assistant Lecturer in Physics at, 278
Southern: Equatorial Africa, Proposed Compilation of a Geological Map of, 438; Rhodesian Geology, R. Tyndall-Biscoe, 971; Whaling, Sir Sidney F. Harmer, 292
Soviet Science, Prof. F. S. Marvin, 170
Space Lattice? A Two-Dimensional: Dr. R. C. Menzies, 907; W. Baker, 1078
Spark, Formation of a, F. G. Dunnington, 1081
Sparrows, London, Degeneracy in, 180
Spatial Distance in General Relativity, On the Definition of, H. S. Ruse, 882
Special Libraries and Information Bureaux, Association of, 644
Spectra, Index of, late Dr. W. Marshall Watts. Appendix Z: Iron and Iron Oxide, 1060
Spectrum: Se III., The Structure of the, J. S. Badami and Dr. K. R. Rao, 496; Sensibility of Photoelectric Cells, Extension of the, under the Action of Oxygen, G. Dejardin, 83
Speech and Music, Reproduction of, Modern Apparatus for the, Dr. N. W. McLachlan, 517
'Spekker' Photometer, The, for Ultra-Violet Spectrophotometry, F. Twyman, 770
Spektroscopie, Handbuch der, Prof. H. Kayser und Prof. H. Konen. Band 7, Lief. 2, 1061
Spherical Astronomy, Text-Book on, Prof. W. M. Smart, 207
Sp. hispanicum var. *marocanum*, The Jackal and Hedgehog Reservoirs of, P. Delanoë, 770
Spiral Nebulæ, The Apparent Recession of the, M. L. Humason, 461
Spiriferidæ, The British Carboniferous Reticulate, T. N. George, 1012
Squilla, Anal Gland of, T. Komai and Y. M. Tung, 762
Stainless Metals, Sir Harold Carpenter, 382
Star: Apparent Diameter of a, Calculation of the, P. Rossier, 734; Density in Different Galactic Latitudes, P. J. Melotte, 192
Stars: Collapsed, and Novæ, Prof. E. A. Milne, 587; Double: Catalogue of, 1045; Measures of, Prof. F. P. Leavenworth. With which are included the Measures by W. O. Beal, 743; in their Courses, The, Sir James Jeans, 615, of High Luminosity, The, Cecilia H. Payne, 615; White Dwarf: Constitution of, Seitarô Suzuki, 838; The Internal Temperature of, Prof. E. A. Milne, 999; with Nebulæ, Impact of, K. Hirayama, 156
Statistics and Actuarial Science, Some Recent Researches in the Theory of, Prof. J. F. Steffensen, 286
Steel: Industry, the British Heavy, Prof. H. Stanley Jevons, 678; Mild, in Hot-galvanising, Attack on, E. J. Daniels, 594
Stellar: Energy, Atomic Synthesis and, Dr. R. d'E. Atkinson, 194; Photometry, A. S. Fairley, 461; Rotation, Dr. E. A. Kreiken, 308; Velocities, Measurement of, Absorption Spectra of Crystals at Low Temperatures as References in the, S. Freed, 33
Stereoisomerism of Derivatives of 1:1′-dinaphthyl, A. Corbellini, 1014
Sterilisation: and Mental Deficiency, 129; Human, pamphlet on, 111
Sternkunde: Die Geschichte der, von den ersten Anfangen bis zur Gegenwart, Prof. E. Zinner, 986
Stipa nitida, The Autecology of, T. G. B. Osborn, J. G. Wood, and T. B. Paltridge, 918
Stocks, Ever-sporting, A Satellite missing from, Dr. J. Philp and Prof. C. L. Huskins, 970
Storm of July 24, 1930, in the Treviso-Udine District: A. Puppo, 199; A. Puppo and P. Longo, 466
Strangeways Research Laboratory, Cambridge, Report of the, 792
Stratified Clouds: Electrical Conditions in, Dr. M. Graham, 969; The Forms of, Part 1: Experimental; Part 2: Discussion, Sir Gilbert Walker and A. C. Phillips, 917
Stratigraphy, General, Prof. J. W. Gregory and B. H. Barrett, 945
Streaks in Chemical Studies, E. Schally (4), 468
Street: Lighting: Tests on, 996; The British Standard Specification for, C. C. Paterson, 488; Traffic: Control by Visual Signals, 180; Engineering, Dr. M. McClintock, 1033
Stresses: in Welded and Riveted Connexions, Distribution of, W. Hovgaard, 555; in Wheels, Prof. E. G. Coker, 174
Stretta, The Struggle of Cereals against, R. Perotti, 735
Strontium and Barium, New Isotopes of, Dr. F. W. Aston, 221
Strukturbericht, 1913–1928, P. P. Ewald und C. Hermann, 511

Strychnos henningsii, The Alkaloids of the Bark of, M. Rindl, 200
'Sub-genes', A Hypothesis of, Sturtevant and Schultz, 273
Sudanese Kingdom: A, an Ethnographical Study of the Jukun-speaking Peoples of Nigeria, C. K. Meek, 285
Sugar Cane: -Breeding Stations, proposed, 181; Mosaic, Immunity to, acquired by the Host, E. M. East, 555; Research Conference, Imperial, 1931, 160
Sugars from Human Milk, Two New, Gyrolactose and Allolactose, M. Polonovski and A. Lespagnol, 125
Sulphides of the Rare Earths, Study of some, Picon and Cogné, 882
Sulphur: and Growth, L. Binet and J. Magrou, 466; The Photochemical Oxidation of, R. Dubrisay and R. Pallu, 646
Sulphuric Acid, The Comparative Hydration of, and of the Alkaline Bisulphates, J. B. Senderens, 199

SUPPLEMENT.
Standards of Measurement: Their History and Development. By Sir Richard Glazebrook, K.C.B., F.R.S. . . . 17

Safety Work in Chemical Industries.

THE common impression that chemical industry is exceptionally dangerous is largely derived from such disasters as the serious explosion at the Royal Naval Cordite Factory, Holton Heath, on June 23, in which ten men were killed and three seriously injured. Like the Castleford disaster of last year, the explosion originated in the nitrating house, and indicates the devastating effects of chemical processes which are allowed to get out of control.

In spite of the poisonous and dangerous materials and the high temperatures and pressures which are frequently used, the accident rate in chemical industry compares very favourably with that of other industries, in a number of which both the frequency rate and the severity rate of accidents are considerably higher. This position is the result not only of experience but also of accurate and scientific control of the manufacturing processes. Chemical manufacturers are now well aware of the dangers connected with their industry, and take every possible step to reduce the number of accidents in chemical industry and develop adequate safety measures.

It is, indeed, significant that even in processes which to the ordinary person appear to involve the greatest risks, the accident rate, as a result of exceptionally strict control, is even lower than normal. The price of safety is unceasing vigilance, and the characteristic of chemical industry is not a high accident rate, but the appalling consequences which may attend the single slip or oversight on the part of the human element, which is responsible for 90 per cent of industrial accidents. The Castleford disaster may apparently be traced to the neglect to sample the waste acid storage tanks in the ordinary way, the Home Office inspectors observing that proper sampling might have led to detection of the presence of the nitro-compound in the acid mixer and allowed suitable precautions to be taken.

Even the strictest control may, however, at times be thwarted by some abnormal conditions, and if, as at Holton Heath, responsible officials such as the chemist in charge perish in the explosion, or, as at Chatterley, Stoke-on-Trent, on June 3, lose their lives in attempts at its control, it is difficult to detect the abnormal circumstances responsible and devise precautions to prevent its recurrence. This emphasises both the need for research into the causes of accidents and the importance of correlating, by publication, abstracting, and indexing, the information obtained by research or other means.

As noted in a recent article in NATURE (May 30, p. 805), to this formidable problem scientific workers have as yet given inadequate attention. Much valuable work has already been done, especially in chemical industry, which compares very favourably with other industries. In Germany, the work of the Berufsgenossenschaft der chemische Industrie is well known, and its publication in *Die chemische Industrie* of illustrated notes on accidents, safety precautions, and devices compiled by the technical inspectors receives a wide circulation. In Great Britain, the efforts of the Association of British Chemical Manufacturers, which in the last two years has undertaken the task of abstracting, indexing, and publishing safety information pertaining to chemical industry, are by no means so well known as they should be. The Association has published quarterly, since January 1930, a classified summary of safety information, derived not only from published literature but also from the records of the Association. The latter include information supplied privately by members of the Association, and this adds very considerably to their value. The wider the membership of the Association, and the more fully its members co-operate in this work by pooling their information on safety matters, the more effective and invaluable its Safety Summary will become.

In addition to the Safety Summary, the Association of British Chemical Manufacturers has for several years published what are termed " Safety Circulars ". These are single sheets dealing with accidents which either present some unusual feature or indicate some useful precaution. The circular usually describes briefly the accident and its cause, and gives the views of the Works Technical Committee of the Association as to the precautions necessary to avoid repetition of the accident. Recent circulars have dealt with the escape of sulphuric acid in transfer by air pressure from a tank waggon to a raised storage tank, fires at a tar distillation plant and benzole plant, the bursting of a drum of phenol by compressed air, and fires at cellulose spraying plants. Such circulars are obviously of an interest which is not confined to chemical industry in the narrower sense. This is recognised by the Association, which holds the view that safety information, like medical science, should receive the widest possible publication. Accordingly, not only has a system of co-operation been arranged for the pooling of information with French and German colleagues, but also the benefits of its safety service are available to non-members on payment of a suitable fee.

A further feature of the safety work of the Association of British Chemical Manufacturers is the " Model Safety Rules for Chemical Works ", of which Part 1 and a first section of Part 2 have already been issued to its members. These rules, as indicated by Mr. J. Davidson Pratt in his recent address on " The Cleaning and Repair of Plant and Vessels containing Dangerous Materials " at the Chemical Session in the National Safety First Week at Leeds, in some respects go beyond the Chemical Works Regulations issued by the Home Office. The addition to which Mr. Pratt particularly referred was intended to prevent misunderstanding where the full implications of the regulations regarding the thorough removal of dangerous material might conceivably be overlooked.

In his paper, Mr. Pratt outlines the main types of risk attached to the cleaning of containers and the chief precautions to be taken. While the details to be followed may vary widely with different materials and classes of vessel, certain general principles can be enunciated. For these the widest publicity is desirable, especially since volatile and dangerous solvents are now widely used in industries where the scientific knowledge and control is by no means so prominent as in chemical industry. In such industries the design of plant to facilitate safe cleaning may be completely overlooked and the question of responsibility assumes great importance.

Even in chemical industry the term ' responsible person ' does not always receive an interpretation consistent with its use in the Chemical Works Regulations. Many serious accidents have occurred because the testing of stills or containers prior to repair work or entry by workmen has been entrusted to persons without adequate scientific knowledge. Under modern conditions, industrial safety requires the employment in industry generally of larger numbers of chemists and other responsible scientific workers. Under-staffing on the scientific side definitely increases the risks of operatives, and while it is probable that some delegation of responsibility is unavoidable under industrial conditions, the scientific and technical staff should be adequate to ensure thorough training of, and personal contact with, those to whom such responsibility is at any time delegated. It was a public-spirited policy which led the organisers of the British Association of Chemists to include in its programme the endeavour to secure legislation providing that certain prescribed operations should be under the direct control and supervision of a qualified chemist. While in practice such operations can frequently be carried out by well-trained assistants, their efficiency, especially from the safety point of view, depends upon uninterrupted personal contact with a responsible chemist upon whose experience and knowledge they can draw at once in emergency.

Radioactivity and the Atomic Nucleus.

Radiations from Radioactive Substances. By Sir Ernest Rutherford, Dr. James Chadwick, and Dr. C. D. Ellis. Pp. xii + 588. (Cambridge: At the University Press, 1930.) 25*s.* net.

THE appearance of a new book on radioactivity by Lord Rutherford and his associates is a noteworthy event in the world of physics. Rather than prepare a new edition of his standard treatise on "Radioactive Substances and their Radiations", the senior author has chosen to devote his present discussion primarily to the significant developments in radioactivity which have occurred since that treatise appeared. These developments deal primarily with the characteristics of the radiations from radioactive materials and the effects which they produce. In view of the present state of physics, and the fundamental questions associated with the outer part of the atom apparently well understood, and the atomic nucleus offering perhaps the most vital problem with which physics is now faced, we are fortunate to be presented with this clear and comprehensive account of the information regarding the nucleus which is afforded by studies in radioactivity. Nothing could be more timely.

One is impressed by the extent of the important information that has come from recent studies in radioactivity. Thus, among other things, discussions are found of the disintegration of atoms by alpha ray bombardment; the studies of nuclear charge and nuclear size by the scattering of alpha rays; the discovery of rare alpha, beta, and gamma particles of extraordinarily large energy, revealing hitherto unsuspected types of disintegration; the quantum mechanics theory which describes how radioactive disintegration is possible; magnetic beta ray spectra, and their associated gamma ray spectra, revealing nuclear energy levels and evidence that electrons as discrete entities may not exist within the nucleus; crystal measurements of gamma ray wave-lengths, and the precise confirmation of Einstein's photoelectric equation at very high frequencies; recent quantum theories of gamma ray scattering; experiments with cosmic rays and their significance regarding the origin of the rays. Many of these developments have resulted from the labours of the authors themselves, and none could be found better qualified to describe them.

Gradually our knowledge regarding the atomic nucleus becomes more precise. Experiments with scattered alpha rays have shown its minute size and its relative large mass. They have enabled us to measure its charge, and even to estimate the field of electric force in its neighbourhood. Further information on the latter point is given by the speed with which the alpha particles are ejected from the radioactive nucleus. Combining the evidence from these alpha ray experiments, it becomes evident that surrounding the nucleus there is a 'potential wall', which prevents alpha particles that are outside from entering the nucleus and those on the inside from escaping. We are thus afforded a basis for developing a quantum theory of radioactive disintegration according to which the probability of an alpha particle jumping this wall is greater if it has large energy, and a qualitative explanation of one of the fundamental laws of radioactivity is obtained. Studies of the sharpness of gamma ray lines suggest a nucleus in which planetary alpha particles correspond to the electrons of the outer atom; though how these particles are held together remains unknown. Similarly, the condition of the electrons in the nucleus remains unsolved. There is no gamma radiation that can be traced to these electrons, and when they appear as beta particles their energies are distributed over broad bands. Though much new light is shed by these studies in radioactivity, the nucleus of the atom, with its hoard of energy, thus continues to present us with a fascinating mystery.

It is inevitable that in an undertaking of this magnitude not all parts of the treatment can be kept strictly up to date. Thus, for example, in discussing the spectra of gamma rays from crystals, though the important work of Thibaud (1925) and Frilley (1928) is mentioned, that of Steadman (1929), which reveals gamma rays of frequency much higher even than those observed with the magnetic spectrometer, is not referred to. The impression is, nevertheless, that the authors have covered the field with great thoroughness, and have made careful selection of the material that is included.

For those who are familiar with Rutherford's style from his earlier writings, it is superfluous to mention the clarity and succinctness of his portion of the present book. Dr. Chadwick and Dr. Ellis are, however, to be congratulated in having caught something of the senior author's lucidity of expression. The result is a well-balanced discussion which the novitiate will find readable, and those working in the same field will find a mine of suggestive ideas and authoritative information.

ARTHUR H. COMPTON.

Man's Remote Ancestry.

The Origin of the Human Skeleton: an Introduction to Human Osteology. By Dr. Robert Broom. Pp. 164. (London: H. F. and G. Witherby, 1930.) 10*s.* 6*d.* net.

WHEN, nearly forty years ago, Dr. Broom went to Australia to study the most primitive mammals now surviving, very little that was more than conjecture was known of the origin of mammals. As the result of his researches on the comparative anatomy of the Australian monotremes and marsupials and the examination of the rich harvest of fossils that has rewarded his thirty-four years of searching in South Africa, he has recovered so many links between the most primitive reptiles and mammals as to be justified in claiming, as he does in this book, that the essential problem of the origin of mammals is now definitely solved. Incidentally also, the question of the origin of lizards and crocodiles has been answered, and new light has been thrown upon the ancestry of dinosaurs and birds.

It is not surprising that the man who has contributed so largely to these great achievements, and himself recovered in the field most of the material which made them possible, should be able to write with freshness and originality, with a disregard for traditional views and pedantry, on the subject of his lifework. In this small book, Dr. Broom gives a concise and wonderfully simple and convincing account of the information afforded by the comparative anatomy of the skeleton in vertebrates to demonstrate the line of evolution leading to reptiles, the derivation of mammals from one of the reptilian groups (Ictidosauria) at the close of the Triassic, and the origin of the Primates from a primitive Menotyphlous mammal before the end of the Cretaceous.

In the process of building up his argument, Dr. Broom examines in turn the comparative anatomy of the skull, the vertebræ and sternum, and the limbs, and thus incidentally has written in bold outline a most fascinating story of "the origin of the human skeleton", which is the descriptive label he has given his book. His wise selection, no less than his boldness and courage, eliminates most of the puzzling complexities of a difficult subject, and has enabled him to write with full mastery and lucidity a surprisingly easy and stimulating narrative. Whether or not this drastic re-interpretation of our knowledge will stand the test of critical analysis is, at the moment, of less importance than the consideration that a mass of new information is skilfully woven into the fabric of an easily comprehended hypothesis, which will provide the student with a clear-cut scheme wherewith to test the evidence, as well as the scheme itself, the brilliant hypothesis which Dr. Broom has constructed in tentative interpretation of the facts. This masterly synthesis is a conspicuous contribution to the study of the origin of mammals and of the evolution of man, which every student of human and comparative anatomy should assimilate.

G. ELLIOT SMITH.

Gold Resources of the World.

The Gold Resources of the World: an Inquiry made upon the Initiation of the Organising Committee of the XV International Geological Congress, South Africa, 1929. With a Summary by A. C. Sutherland. Pp. xiv + 457 + 38 plates. (Pretoria: Wallach's, Ltd., 1930.) 25*s.*

IN 1929 the fifteenth International Geological Congress met in South Africa—synchronising as to time with the meeting of the British Association. The organising committee of the Congress had decided beforehand to initiate an inquiry into the gold resources of the world, as it was felt that such a subject was singularly appropriate. Previous congresses had dealt with the world's resources of iron ore, coal, and pyrites, and these reports are still looked upon as standard works of reference. The Prime Minister of the Union, General Hertzog—who was honorary president of the Congress—issued a circular letter on Oct. 31, 1927, asking for the assistance and co-operation of those countries which have ever been known producers, and the reports are set out in this volume. There are also innumerable maps and useful statistical tables.

Let it be said that, on the whole, these reports are extraordinarily well done, and the names of their respective authors are a guarantee of accuracy, so far as this is possible. An introduction by Dr. A. L. Hall, a member of the staff of the Geological Survey of the Union, who acted as general secretary of the Congress, explains the scope of the work, and a most informative summary of the reports by Mr. A. C. Sutherland, formerly mine surveyor on the staff of the Union Government Mining Engineer, gives all the information which the casual reader would wish to have. So far as one can see, no country has been omitted, and although the same degree of accuracy, or rather approximation to accuracy, cannot be claimed for the gold resources report as for the previous three which have already been mentioned, it can be said that it is the best which can be done.

Gold has always been the premier precious metal. Mythology, the classics, and the Bible all teem with references to it, but never has it been talked about so much as to-day. True, the economists differ as to its utility, and one hears criticisms concerning its distribution, but all are agreed that it is the basis of the monetary system of most of the important countries of the world. It is also the yard-stick whereby wealth is measured and consequently the basis of credit. Yet, contrary to popular opinion, it is merely a commodity, subject like all others to ordinary economic laws, and when it costs a mine twenty-one shillings to recover gold from one ton of ore which contains only twenty shillingsworth of gold, the mine which has that ore must assuredly go out of business. Moreover, with all the searching during the centuries—and the search still continues—no other metal or commodity seems capable of taking its place.

No wonder, therefore, that there have been gold rushes in California, Australia, the Klondike, and in South Africa; and these will continue. True, we do not hear of them so much to-day, because our old world has been fairly well prospected during the past fifty years. But one would not expect to hear of a gold rush in Ireland, yet it is well known that there is plenty of alluvial gold in County Wicklow, and there was a veritable rush there in 1795, when 800 oz. were recovered by peasants in six weeks. The summary already referred to shows that the British Empire is responsible for more than 70 per cent of the world's production, the Transvaal itself accounting for more than 50 per cent. Gold was first discovered in Bechuanaland by Carl Mauch in 1866; and since returns were made, the recorded value of the Transvaal output alone is now more than one thousand million pounds. The United States, which has long been out of the race for the premier position, is only a little way behind South Africa, and Australia comes next, with a total value of about six hundred millions.

Dr. Pirow, Government Mining Engineer to the Union of South Africa, on page 337 makes the following remarkable statement: "Since the year 1884, prior to which date no reliable figures are available, the Union of South Africa has produced a total of 229,051,118 fine ounces of gold, equivalent to 22·4 per cent of the total estimated world production to date, or 34 per cent of the production since the Union first entered the list of gold producers".

Though gold is widely distributed, the countries which have contributed substantially to the world's store in the past are comparatively few in number and some of them have ceased production altogether. Australia has fallen from its high position, but that is due entirely to political causes. When these are removed, it is possible that this great country may again become one of the principal producers.

The economist of the orthodox school will naturally be more interested in reserves rather than production, and this is possibly the weakest part of the reports. It has to be recognised, however, that these depend on economic considerations, and the zero line of payability is, therefore, never constant. It appears, however, that it is to the British Empire, and more particularly to South Africa, Canada, and to a lesser extent to Australia, that the world must look for its future supplies. In the Transvaal alone it is quite possible that gold to the value of one thousand million pounds may still be won—a stupendous total. There is no report from Panama, but that country's prospects as a producer appear to be good.

It remains to be said that the printers are the well-known South African firm of Wallach's, of Pretoria, which is the administrative capital of South Africa. But Pretoria is not a large city, and as the reports are printed in English, German, and French—the three official languages—and one in Italian, the production is indeed a remarkable tribute to their ability.

WM. CULLEN.

Short Reviews.

Bergey's Manual of Determinative Bacteriology · a Key for the Identification of Organisms of the Class Schizomycetes. By David H. Bergey, assisted by a Committee of the Society of American Bacteriologists, Francis C. Harrison, Robert S. Breed, Bernard W. Hammer, Frank M. Huntoon, with an Index by Robert S. Breed. Third edition. Pp. xviii + 589. (London: Baillière, Tindall and Cox, 1930.) 27*s.* net.

This publication, which has now reached its third edition, is an extension and elaboration of the admirable and painstaking work of the Committee on Characterisation and Classification of the Society of American Bacteriologists (1917, 1920). When one considers the labour involved in a compilation of this nature, it would be agreeable if one could be persuaded that the value of the results obtained is commensurate with the effort expended. But even the most cursory examination of the pages of this manual suggest that too much is taken for granted in the published descriptions of various micro-organisms.

When, for example, one finds organisms of almost precisely the same morphological, cultural, and biochemical characters and of serological identity classified, not only under separate species but even under separate genera (*Pseudomonas fluorescens* and *Phytomonas* spp.; *Pseudomonas aeruginosa* and *Phytomonas aptata*; *Corynebacterium pseudotuberculosis* and *Shigella pfaffi*), one wonders where the authors' taxonomic conceptions may eventually lead us. The closely related species, *B. whitmori* and *B. mallei*, are, moreover, included in separate genera (*Flavobacterium* and *Pfeifferella* respectively), and the genus *Shigella*, in addition to *S. pfaffi* mentioned above, is made to include a rough variant of *Salmonella gallinarum* (*Shigella jeffersonii*). Turning to the genus *Salmonella* itself, one finds that practically no attention has been paid to the mass of brilliant and elaborate research made in recent years that has thrown so much light upon the complex serological relations of this extremely natural and self-contained group of bacteria.

A comprehensive and critical revision of the text would appear to be necessary when the next edition of this work is contemplated.

R. St. J.-B.

Textbook of Logic. By Prof. A. Wolf. Pp. 407. (London: George Allen and Unwin, Ltd., 1930.) 10*s.* net.

The best text-book on a special subject is not always written by the scholar with the greatest reputation in that subject. It is gratifying, therefore, that a logician of Prof. Wolf's measure should have written a text-book which can unhesitatingly be put in the first rank.

Logic in the past has too often erred on the side of mechanical formalism and remained to the student out of all relation to common sense and practical needs. In the author's own words, it has become "the recruiting place for the sadly depleted philosophy classes". Prof. Wolf, whose very position at the London School of Economics keeps him in touch with most of the sociological and humanistic developments of the day, is emphatically alive to the practical needs of the student and scholar alike. His close contact with social science makes his treatment of logic fruitful in the application to modern types of argument, while the style is lucid and pleasant, and the treatment, in spite of its full dose of symbolism and technical instruction, distinctly attractive.

The exercises, given at the end of the book and therefore not impeding the continuity of the argument, will enable the student to apply the sound principle of the author that logic, no more than algebra or geometry, can be mastered by reading alone.

Pioneers of Public Health: the Story of some Benefactors of the Human Race. By M. E. M. Walker. Pp. xv + 270 + 23 plates. (Edinburgh and London: Oliver and Boyd, 1930.) 12*s.* 6*d.* net.

The pioneers whom Mrs. Walker has chosen to commemorate are the twenty-one eminent men whose names adorn the walls of the new building of the London School of Hygiene and Tropical Medicine, a drawing of which forms the frontispiece. As Sir Humphry Rolleston points out in the foreword, twelve of the pioneers are British, four are from the United States, three from Central Europe, and two from France. Among the various departments of public health, epidemiology and State medicine are represented by Thomas Sydenham, Lemuel Shattuck, Sir Edwin Chadwick, William Farr, Sir John Simon, and Hermann Biggs; naval and military hygiene by James Lind, Sir John Pringle, and Edmund Alexander Parkes; preventive medicine by Johann Peter Frank, Edward Jenner, Max von Pettenkofer, Major Walter Reed, and General William Crawford Gorgas; bacteriology by Pasteur, Lister, and Koch; and protozoology by Surgeon-Major Timothy Richards, Lewis Alphonse Laveran, Sir Patrick Manson, and Sir William Leishman. A concise but sympathetic account of each pioneer is accompanied by his portrait and followed by a brief list of references.

L'Esprit et ses maladies. Par Marcel Nathan. (Bibliothèque générale illustrée, 15.) Pp. 80 + 60 planches. (Paris: Les Éditions Rieder, 1930.) 20 francs.

Dr. Nathan provides us with an excellent summary of the prevailing French attitude towards the mind and its diseases. He divides his small book up into three sections: the brain and the mind, the so-called organic psychoses, and the so-called functional psychoses. To include mania and melancholia as functional or non-organic conditions in the present state of our knowledge is scarcely justifiable. They are probably of metabolic origin. The best part of the book is the illustrations, some of which are actual photographs of patients, while others are reproductions of well-known pictures, by various Continental artists.

The Beginnings of Science.*

By Dr. Charles Singer.

When did science begin? Can any question be more fundamental for the history of rational thought? An adequate answer would doubtless demand the formulation of an exact and generally acceptable definition of science. No one, perhaps, has yet succeeded in accomplishing this seemingly simple task. But without insisting on a precise delimitation of the term 'science', we may get some way, at least, by taking its current if inexact sense. Thus we may treat science as simply the systematic *process* of recording natural happenings with the object of discerning some relation between them.

I would emphasise the word *process*. Science is often discussed as though it could be presented as a body of knowledge or doctrine, but reflection will soon reveal that this point of view cannot be maintained. For is it not the case that science that has ceased to develop soon ceases to be science at all? The science of one age is often the nonsense of the next. Think, for example, of judicial astrology, or of the doctrine of lucky and unlucky numbers. Who, if he did not know their history, would recognise these as the debris of finely conceived and far-reaching scientific hypotheses, which once attracted clear-thinking minds seeking for rational explanations of the world in which they lived? We may smile, if we will, at such an explanation of the face of the earth as the doctrine of successive disasters followed by successive creations. The view that fossils are the early and clumsier attempts of an omnipotent Creator may even move us to theological wrath. Yet such conceptions were but stages in the development of geological ideas, just as the scientific views of our own time are but a stage in a great secular process which will continue when we are no more.

It therefore behoves the historian of science to be very charitable, very forbearing, in all his judgments and presentations. He must not ask too much of previous ages, nor must he judge them by the standards of his own. He needs constantly to recall that he is dealing with work of erring and imperfect human beings, each of whom had, like himself, only a very partial view of truth. There is an unquenchable and irresistible tendency innate in the human mind to erect general laws or rules in explanation of the happenings of the world. That tendency is no less present in the historian of science than in the great minds whose work he records, and if he is to be judged at all by posterity, he can but echo the epitaph:

> Reader, thou that passest by,
> As thou art so once was I;
> As I am, so shalt thou be,
> Wherefore, reader, pray for me.

Time, still, like an ever-rolling stream, bears all its sons away. It is the stream itself and the spirit that dwells therein that the historian of science has to study.

Science, then, is a process that can be followed through the ages; it is not a mere passive body of knowledge. The sheer validity and success of the scientific process, as applied in our own time in western Europe and America, has given rise to popular misunderstanding as to the nature of science, and some misapplication of such terms as 'science' and 'scientific'. We hear of the *science* of some prize-fighter, and a book has been published on the "Science of the Sacraments". There is nothing in the laws of this or any other country which forbids its citizens from giving the words of their language such significance as they may choose, but the word *science* as employed in these connotations has no clear link with the great progressive method of acquiring knowledge with which the historian of science has to deal. The very form of the adjective from science might itself give pause to those who would force the word to cover such topics as the skill of the prize-fighter or a knowledge of the theory and practice of religious rites. The word *scientific* means, derivationally, *knowledge making*, and no body of doctrine which is not being progressively *made* can for long retain scientific attributes.

During the last two generations the evolutionary conception of Nature has become so general that it now pervades our thoughts on every aspect of living activity, nor can we understand an organic product until we know how it came to be what it is. Now, the efforts of the human mind are essentially such products. It has thus become generally recognised that to comprehend, for example, the constitution of a State or the teaching of a religion it is absolutely necessary to know its past. This is the true reaction of evolutionary doctrine on the study of history.

On the study of science itself, however, this reaction of evolutionary doctrine has been less generally recognised. Why this should be is perhaps not altogether clear. One reason may be that the triumphant and absorbing successes of the application of the scientific method have deflected attention from the process itself. Another reason, which is perhaps but a restatement of the former, is that the very rapid growth of the products of the scientific process in quite modern times has turned men's thoughts away from its more ancient achievements. Yet it is clear that if we would understand the process itself, we must examine its application in the past and watch its action under conditions different from those in which we ourselves live. Only thus can we hope to attain any real insight into the nature of the process and of the effect it has had on man's estate throughout the ages.

Among the criticisms that can be made of any attempt to trace the history of science, there is one that should be met at the outset. It has been said that the history of scientific activity presents a field so vast that it cannot be compassed at first hand by any single mind. The criticism is without validity. If pressed, it would not only prevent the writing of the history of science, but would also prevent the writing both of history and of science. Who, of his own knowledge, can compass the history of even a single country? Who, of his own knowledge, can deal with the animal kingdom, with the science of geometry, or with the structure of the earth? Yet this has not prevented, and should not prevent, the writing of histories of England and of Europe, of works on zoology, of treatises on mathematics, or of text-books of geology. The scope of such books in reference to the first-hand knowledge of their writers must be effectively infinite. The difficulty in writing them—as in reading them—is the difficulty in getting a philosophical grasp of the principles involved. In obtaining such grasp, first-hand knowledge is of primary importance. Yet this knowledge, applied in such a field, is but a means to an end, and the writer must be judged by his grasp of the principles he sets forth, rather than by the actual number of experiments he has made or experiences that he has undergone.

---

* Inaugural address delivered to the Second International Congress of the History of Science and Technology, by the president, on June 29, at the Royal Geographical Society.

But to return to our question as to when science began. The question can as little be answered as the question, When does a man begin to grow old? "Before that I to be begun, I did begin to be undone." Anthropologists have detected germs of the scientific process in the lowest and rudest races of mankind. As soon as a child begins to observe, he begins to make generalisations. The savage sees the action of a living thing in the wind and the flow of the water. He generalises from his imperfect observation that movement means life. The baby calls every male "daddy"; his, too, is an elementary generalisation based on imperfect experience. Both ascriptions are imperfect attempts at deducing laws.

Here, however, we encounter a real gap in the historical narrative. We can see the scientific element in the baby's generalisation or in the savage's belief. Yet we cannot, with any confidence, trace them forward in a continuous stream to anything that we should call science in the current use of that term. How far, then, can we trace the matter the other way, ascending the stream of time? In this attempt the last decade has been particularly fruitful, and I shall venture to devote the remainder of my remarks to the special nature of this recent historical achievement. As is too often the case on the scientific front, the pioneers are more concerned with their own progress than with the relation of their advances to those of others. The onlooker truly sees most of the game, and perhaps it is not going too far to say that the game cannot be clearly seen except by the onlooker. This is the justification of the professed historian of science. Without him research in one department would rapidly lose touch with research in other departments. This is so with recent scientific history. Let us seek in the same spirit among the records of a far earlier scientific history.

As we trace the records of science back into the mists that shroud the dawn of history, we see its varied disciplines dwindling to two, namely, to medicine and mathematics. So far as complete works are concerned, the earliest of all scientific treatises that have come down to us are in the medical class. They are contained in the miscellaneous group of tracts known as the "Hippocratic Collection".

The "Hippocratic Collection" takes its name from the alleged 'father of medicine'. In a less critical age this mass of writings was all ascribed to Hippocrates, and there are some who still find it difficult to abandon the old paths. Nevertheless, there is no evidence, worthy of the name, that any part of any of these works was written by Hippocrates, nor indeed is there any real evidence that Hippocrates wrote anything. It is, however, certain that some works in the "Hippocratic Collection" were composed in the fifth century B.C., at which period their eponymous author was born. Sections of some of them may well date back to the sixth, and portions of them even to the seventh century. Moreover, it has long been recognised that these medical writings were an integral part of a far wider and more deeply based contemporary rational movement in philosophy.[1]

It has indeed been argued that the relations between the medical and historical writings of ancient Greece are closely paralleled by the relations between the evolutionary and historical writings of a generation or two ago. We might put it that Hippocrates was to Thucydides as Darwin was to Buckle or Lecky. A good case for the comparison has been made recently by Prof. Cochrane of Toronto.[2]

However this may be, it is evident that behind these earliest surviving scientific monuments of the fifth, sixth, and seventh pre-Christian centuries there must be a scientific tradition that was already ancient when the Greek world was still young. Of this more ancient rational tradition the mathematical fragments have been more successfully pieced together than the medical.[3] Thus we have details of the achievements of the followers of Pythagoras, and perhaps of Pythagoras himself, whose life occupied the greater part of the sixth century. Moreover, Thales, the sage of Miletus, of whose scientific achievements there can be no doubt, takes us yet further back and into the seventh century. He takes us, too, beyond Greece, for his mother was a Phœnician. He himself had travelled in Egypt. Phœnicia suggests contact with Mesopotamia and the ancient Sumerian civilisation. Recent discoveries in that region, notably those that deal with the treatment of metals, suggest a command of natural forces which demanded theoretical scientific knowledge. Yet it is to Egypt that the Greeks commonly ascribed the origin of their medical and mathematical knowledge.

Among the Greeks before Thales and the seventh century, our view of the rational spirit grows very dim. In the "Works and Days" of Hesiod, written in the eighth century B.C., we get some astronomical lore. Such knowledge, however, must have been common property in the Near East, and indeed in every early agricultural community. In the absence of an adequate calendar, some astronomical knowledge is necessary for the elementary operations in the field. Hesiod, it is true, has something rather beyond farmers' astronomy, but in him we have the independent scientific element at a well-nigh irreducible minimum.

Can we, then, trace the rational tradition among the Greeks behind Hesiod and the eighth century ? I think we can. In the Iliad of Homer we obtain glimpses, distant, it is true, of an independent rational medical system. The Iliad tells of a great deal of fighting, in the course of which no less than 147 wounds are well described, and in many cases their treatment detailed. Now this treatment is always on entirely rational grounds, and magical elements are conspicuous by their absence. This and many other hints in the Iliad imply the practice of scientific medicine by recognised practitioners, without relation to folk-medicine. Thus, with the aid of the Iliad, we may trace the scientific tradition among the Greeks as far back as the ninth or tenth century. It is noteworthy that in the Odyssey the origin of medicines is ascribed to Egypt.

In view of the consensus among the Greeks as to their debt to Egypt, all traces of the scientific spirit revealed in the Egyptian papyri are of peculiar interest. Yet the finds have been, till recently, extraordinarily disappointing, and the contrast between Greek science and Egyptian science is greatly to the disadvantage of Egypt. For the inferiority of the Egyptian position as against the Greek, due weight has not always been given to differences in the records of the two civilisations.

First, we have to remember that the picture that we form of Greek thought is derived from the literary remains of the Greek people. That there have been irreparable losses to that literature is true, but the surviving part has come down to our time because it was read by the generations that came between the Greeks and ourselves, and it was read because, by each succeeding age, it was thought to be worth reading. Greek literature, as we have it, is thus, in essence, a selection. It is far otherwise with the Egyptian records. We have here merely what time has spared, and that old reaper has no more discretion with books than he has with the lives of men. He spares what he will and as he will. What kind of literature should we hope to recover from the wreck of our own civilisation ? Daily journalism and trade advertisements occupy many times more bulk, and therefore would have a better chance of survival, than the works of the philosophers and men of science.

Secondly, the remnants that have come down to us from ancient Egypt have mostly been recovered from tombs. They were the kind of things that the men of their day thought suitable to bury with their dead. The commonest of all are, in fact, rolls of the "Book of the Dead". If we had to compare them with something in our own civilisation, they would perhaps correspond to the inscriptions on tombstones, to hymn-books, and to prayers for special occasions. It is true that we have an admixture of other documents, but the proportional distribution of surviving Egyptian writings bears no relation to the proportional distribution of Egyptian interests.

Thirdly, it must be remembered that much surviving Greek literature is from the most vital period of Greek history. On the other hand, the overwhelming mass of Egyptian papyri are from the New or Middle Kingdom, whereas the Old Kingdom was the day of Egyptian power. The later scribes were content with copying earlier material. These later scribes were, moreover, commonly careless and not uncommonly incompetent, and, as it falls out, this was especially the case for the papyri that bear on scientific topics.

Bearing in mind these contrasts in the circumstances of Egyptian and Greek documents, let us turn to the surviving papyri of scientific content. These, like the earliest Greek scientific material, divide naturally into the medical and the mathematical. A number of documents fall into each of the two categories, but most of them are so debased or so trivial that we miss little if we take only the principal specimens. Of these there are two in each class that are of primary importance. In the medical class there is the long known Ebers Papyrus and the recently described Edwin Smith Papyrus. In the mathematical class there is the Rhind Papyrus and the very recently described Moscow Papyrus. These four contain practically all that is known of Egyptian medicine—other than that of a purely magical character—and most that is known of Egyptian mathematics.

The Papyrus Ebers, known for seventy years, is still not completely intelligible. It presents many linguistic difficulties, chief among them being the names of drugs. It is of the New Kingdom, and is generally dated as of the sixteenth century B.C. It is in the main a collection of remedies for various named conditions which are sometimes briefly described. Its general intellectual level is about comparable to an English family receipt book of the seventeenth century, of which several have been published. There is no definite physiological, pathological, or pharmaceutical theory, but there is also little that one can call superstition. The book is taken up with a list of traditional treatments of a more or less disgusting character. That sections are taken from a much older work is evident from a few isolated paragraphs in it that are devoted to anatomy. These are so confused as to be unintelligible, but it is obvious that the scribe is trying to abstract an older and more scientific document.

During the last few months Prof. Breasted, of Chicago, has presented us with his edition of an Egyptian medical document of a somewhat different order.[4] The Edwin Smith Papyrus has had a romantic history, having been originally discovered about the same time, and perhaps in the same tomb, as the Ebers. A series of remarkable circumstances left it in private libraries and unknown to scholars until a few years ago.

In general form the Edwin Smith Papyrus is not unlike the Ebers, in date somewhat similar or a little earlier, and its scribe no less careless and incompetent. He was, however, engaged in copying a document of greater scientific value, and probably of greater antiquity than that which was occupying the scribe of the Ebers Papyrus, for there can be little doubt that the original source of the Edwin Smith Papyrus was of the Old Empire. Moreover, the Edwin Smith Papyrus deals with surgical conditions, and especially injuries, while the Ebers is occupied with diseases. Injuries and their treatment lend themselves to clearer descriptions than do the diseases. We thus have in the Edwin Smith Papyrus a document of high value for comparison with certain works of the "Hippocratic Collection" of about twelve centuries later. Without discussion of details it may be said that through the mist of scribal ignorance and misunderstanding we can see in the Edwin Smith Papyrus an author who not only recorded actual case histories, but was seized at times of the spirit of science; that is to say, he records in order to learn something of the workings of the body as distinct from any attempt to treat his patient. Some of his observations, such as that injuries to the brain on one side result in paralysis of the other side of the body, are repeated in the "Hippocratic Collection", and do, in fact, throw light on the nature of physiological mechanism. The Edwin Smith Papyrus—or at least that part of it which survives—is devoted to injuries about the head. It gives us a glimpse—alas! that it should be so dim—of a lost and more ancient scientific literature to which such magnificent treatises as the "Wounds of the Head" and "Fractures and Dislocations" of the "Hippocratic Collection" may well have been related.

For Egyptian mathematics the most important document is the Rhind Papyrus, which was finely edited a few years ago by Prof. T. E. Peet, of Liverpool.[5] Its age is about that of the Edwin Smith Papyrus, though it is copied from an original of the nineteenth century B.C. It professes to be a 'guide for calculation'. Apart from simple rules for giving the areas of figures enclosed by right lines, we have the measure of a circle from which an estimate of π as 3·16 can be deduced, and a calculation with reference to the proportions of pyramids. In this last a certain relation which, as the Papyrus says, "makes the nature of the figure", is deduced from the side of the square base and vertical height or *per-em-us* as the Papyrus calls it. The word *per-em-us* is doubtless the source of the Greek word *pyramis* and our *pyramid*. The problem clearly links up with the mathematical triumph of Thales in deducing the height of a pyramid from its shadow.

The last scientific document of Egyptian origin to be considered is the Moscow Papyrus, which was only published in full by Prof. Struve a few months ago.[6] It is of the Middle Kingdom and thus older than the others. It contains the determination of the volume of a truncated pyramid and the area of a hemisphere.[7] Both are correct, the latter on the basis of the Egyptian value for π as 3·16. It yet remains to be seen whether these determinations are based on general formulæ—as is believed to be the case by Prof. Struve—or whether they are empirically obtained. If the former, it will be necessary to rewrite the history of ancient science and with it much of ancient philosophy.

The rationalisation of the Greek intellect within a very few centuries has always appeared something of a miracle—an epiphany. On the other hand, an ancient and slowly disintegrating scientific tradition in Egypt or in the Near East would fit in well with what we know of the early history of Greek science. Whether such traditions existed is a question of fact which can only be solved by the Egyptologists or Assyriologists. In the meantime, the Rhind, the Edwin Smith, and the Moscow Papyri have made such a view less fantastic than would have appeared to be the case ten years ago.

[7] The Moscow Papyrus is discussed by Battiscombe Gunn and T. Eric Peet, "Four Geometrical Problems from the Moscow Mathematical Papyrus", *Journal of Egyptian Archæology*, 15, p. 167, Nov. 1929, and Kurt Vogel, "The Truncated Pyramid in Egyptian Mathematics", *Journal of Egyptian Archæology*, 16, p. 242, Nov. 1930. The work of Struve is critically reviewed by T. E. Peet in the *Journal of Egyptian Archæology*, 17, p. 154. May 1931.

Population Problems.

THE second general assembly of the International Union for the Scientific Investigation of Population Problems met in the rooms of the Royal Society of Arts on Monday, June 15, the chair being taken by the president, Prof. Raymond Pearl. Delegates of ten nationalities were present.

During the opening session the president reviewed the work of the Union during the three years of its existence, and claimed, with reason, that the progress made could be regarded as gratifying. Fourteen countries already have National Committees, which function with varying degrees of intensity, whilst in still other countries (Czechoslovakia, Greece, Poland) National Committees are in process of organisation. There are three International Research Commissions receiving funds from the Union and dealing respectively with population and food supply, differential fertility, and the vital statistics of primitive races. In addition, grants have been made to many individuals for investigations which fall outside the scope of these Commissions. Sixty-four per cent of all moneys expended is allocated to research. Nine numbers of the official bulletin have been published.

Election of officers took place, and Sir Charles Close succeeds Prof. Raymond Pearl as president of the Union.

During the morning sessions of the following three days, various modifications of the statutes and regulations shown to be desirable by the experience gained during the past three years were made. The afternoon sessions were devoted to the reading of scientific papers.

Prof. J. D. Black, chairman of the commission dealing with population and food supply, outlined a scheme which had been prepared to serve as a basis for the making of an inventory of the work already done on this particular subject and as a guide in the planning of future research. Prof. Jens Warming, of Copenhagen, discussed the trends in agricultural production in Denmark. In his country the increase of the harvest is greater than the growth of population, and if there should be a shortage of one kind or source of food (for example, grain, as was the case during the War) it is a relatively simple matter to adjust this by curtailing the amounts used for animal fodder.

Prof. P. K. Whelpton, of the Scripps Foundation, said that population increase was declining rapidly in the United States, being 9 per cent in 1930 as against 18 per cent in 1920. Consequently, the age composition had changed considerably in the last decade. The number of children under five has actually declined, while the number of persons over fifty has increased about 25 per cent. This slower growth and trend toward a nation of elders should have marked effects on economic, social, and political life, checking expansion and making for greater conservatism.

Prof. A. L. Bowley, of the London School of Economics, dealt with some economic aspects of the tendency of population in Great Britain. He showed that during the past twenty years wages have increased, especially so in the case of town labourers; so much so that in 1929 such a man in regular work had a wage sufficient to provide the bare necessities for a family of four children under fourteen years of age. Poverty in urban districts is due, not to low wages, but to illness, age, unemployment, incapability, death, or absence of the natural bread-winner. During the same period there has been a progressive change in the constitution of the family. The falling birth-rate since 1914 has resulted in a decrease in the number of child-bearing women, a fall in the number of children, and an increase in the number of old people. With the rise of the real wage and the reduction in the number of children per family, future generations will live in an environment progressively more and more favourable for satisfactory development. Smaller families mean better housing conditions and less competition for employment.

Dr. Karl Edin, of Stockholm, reported further on his study of differential fertility among the social classes. His figures show that in this city fertility tends to rise and not to fall with increase in income. Furthermore, sterility is greater amongst the poor couples. Prof. Eugen Fischer, of the Kaiser Wilhelm Institut für Anthropologie, reported on Dr. Muckermann's studies on differential fertility of the agricultural workers and university teachers in Germany. The conclusion to be derived from this study is that a social group, selected on the basis of intellectual achievement, is incapable of maintaining its numbers. Dr. L. I. Dublin, of the Metropolitan Life Insurance Company of New York, read a paper on the outlook for the American birth-rate. He concludes that the decline of the birth-rate is universal, and results primarily from voluntary control of conception and not from reduced fertility. He assumes that the population of the United States will become stationary in the course of the next generation or two with a birth-rate of 14·28 per thousand, and that, having reached this stationary stage, it will then proceed to decline at a rate that will reduce it to one-half in 300 years, in 161 years, in 108 years, or in 80 years, according to whether or not certain variables operate.

Prof. C. B. Fawcett dealt with some factors of population density. He estimates that the total habitable land area of the world is about 50,000,000 square miles and the approximate population of the world about 2000 million. The mean density of population over all the inhabited land of the world is therefore about forty persons per square mile. The actual distribution of population over the land varies from 680 per square mile in Belgium to 2·2 in Australia. It is difficult, perhaps impossible, to enumerate all the factors causing this wide variation in local densities, but amongst the most important are the following—natural resources of the land, mineral wealth and power, geographical location. Developments in modern transport have led to a readjustment of the balance between local fertility and density of population. Products gained locally are, in the great majority of cases, not used locally, but serve to maintain the population of distant regions; and therefore the age-old tendency for density of population to increase in proportion to fertility of the land has lost much of its strength. In some countries we even find that increase in food production locally is accompanied by a decrease in the agricultural and rural population. There is no indication that the fertile regions of the New World are likely to become the home of densely crowded peasant populations comparable to those of China. Prof. Fawcett argued that in Britain the Poor Laws during the last century and the Unemployment Insurance to-day both have had the unforeseen and undesirable result of restricting freedom in the matter of internal migration. The growth of the town-planning movement and of the consciousness of the need of a well-considered country-planning in many lands indicates the likelihood of a far greater governmental interference in the future.

Prof. J. W. Gregory spoke on some effects of current migration restrictions. During recent years there has been an almost complete suppression of immigration on the part of those countries which formerly received the bulk of European emigrants. One effect of such restriction in the United States is labour shortage, resulting in an increased internal migration of negroes and Mexicans. Higher wages and improved hygienic and social conditions tend to increase the duration of life and reduce the infantile mortality of the negro, and this, with the absence of European immigration, must raise the proportion of negroes in the population. This view was not accepted by several of the American delegates, one of whom instanced the fact that birth control clinics were now being opened and considerably used by the negro population of the Harlem district of New York.

Dr. G. W. Kosmak dealt with the position of the obstetrician in relation to certain aspects of the population problem. He expressed the opinion that certain developments in the practice of obstetrics at the present time may have a not inconsiderable effect in reducing the birth-rate; for example, the increase in operative deliveries, which result in a higher mortality, and at the same time undoubtedly produce increased sterility through infection. He pointed out that the dread of maternal mortality played its part in the encouragement of women to have recourse to birth control.

In a paper on the future of the Belgian population, Prof. Baudhuin, of the University of Louvain, concludes that the population is now approaching its maximum, which it will attain about 1940, when it will number 8,110,000; and that after this there will be a gradual decline, so that in the year 2000 it will be only 5,760,000.

Further interesting papers on this subject were presented by Mr. Lotka, Dr. Wicksell, and others, and, in the concluding sessions, papers dealing with the broader biological aspects of the population problem were presented by Mr. Elton, who dealt with the cyclical variation in the numbers of lemming, Arctic fox, and field mouse population, and by Mr. J. A. Fraser Roberts, who discussed the significance of the results of mass selection in the improvement of the breeds of domesticated animals.

The function of the Union is to discuss such matters as the above dispassionately and scientifically, and it is doing its best to carry out this duty, though somewhat hampered by want of funds. Much of the money which has hitherto been spent on the work of the Union has been presented by generous individuals and institutions in America; it is the turn of other countries to follow such a good example, especially as an excellent opportunity now offers itself. The chairman of the American National Committee, Dr. Louis I. Dublin, informed the general assembly that certain sources in the United States would be prepared to pay to the Union the sum of 5000 dollars a year, for three years, on the condition that a similar total sum was presented to the Union by individuals, or institutions, in other countries. This offer was gratefully accepted by the general assembly. Will not those who are interested help by their subscriptions to make this generous offer available? Subscriptions may be sent to the General Secretary, International Population Union, 46 Catherine Street, Westminster.

Prof. Eugen Fischer extended an invitation, which was unanimously accepted, to the Union to hold its third general assembly in Germany in 1934.

Obituary.

MR. W. F. DENNING.

As announced in NATURE for June 20, the veteran astronomer, Mr. William Frederic Denning, died at Bristol, mainly as the effect of the weakness of age, on June 9 last.

Mr. Denning was world-famous, having a reputation based on careful and assiduous use of the telescope, but known more especially for his naked-eye observation of the flight of meteors and his deduction from them of radiant points that form a large part of contemporary knowledge of this byway of science.

Denning was born on Nov. 25, 1848, at Redpost, near Radstock, in Somerset. When quite a boy the aspect of the night sky had an attraction for him, and at the age of seventeen he became possessed of a $4\frac{1}{4}$-inch refracting telescope, which was followed in 1871 by a 10-inch reflector, with which his more important observations were made. At the period when Denning began his astronomical career, the medium for publications relating to the science was the *Astronomical Register*, a monthly periodical started in 1863, in which astronomers made public their views and observations; and to this Denning began to contribute in 1868, his earliest communications being on the surface of Jupiter and the appearance of its satellites, and others on the visibility of Mercury with the naked eye, which was a subject to which he gave much attention throughout his life. A letter in the issue of December 1868 on his observation of the Leonid meteors of that year is interesting as foreshadowing the main work of his life. In 1869 an organisation known as the Observing Astronomical Society was formed under the auspices of the *Register*, which numbered more than forty active members in its second year, and of this Denning was secretary and treasurer. The pages of the periodical show how well he fulfilled the duties of his office during the few years of the existence of the Society. He was president of the Liverpool Astronomical Society in 1887-88.

Denning did not become a fellow of the Royal Astronomical Society until June 1877, but he contributed several short papers to the *Monthly Notices* before that date, with Mr. Proctor, Mr. Main, or some other as sponsor—among these being notes on the visibility of Mercury as a naked-eye object in the twilight, and of the possibility of seeing Jupiter and Venus in sunshine, which he said he was frequently able to do. The majority of them, however, were records of his observation of luminous meteors, and one communicated in April 1876 is specially to be noted, for it was a determination of twenty-seven radiant points that he had determined from his own observations, and was the first of a series of such papers that he contributed during his career. Reference is made in it to similar lists of radiant points by Greg, Tupman, Herschel (Alexander), and to a committee of the British Association on luminous meteors that had published full reports for several years past—for there were many workers in this field at the time, and Schiaparelli had already put forward his views on the relation between meteor-streams and cometary orbits. It is clear that at the beginning of the nineteenth century shooting stars were considered to be of electrical origin, though aerolites found on the earth were recognised as having come from without. It was not until about 1834 that the significance of meteor radiation was recognised as indicating direction in space, and hence later came the further conclusion that meteors move in orbits around the sun.

Denning evidently determined to associate himself with the band of workers in this new branch of science, and to take his full share in the arduous duty of observing. He has described his plan of working in his paper of May 1890, this being a catalogue of 918 radiant points of shooting stars observed at Bristol:

> "All the observations were made in the open air and from the garden adjoining the house. Attention was almost invariably given to the eastern sky. In mild weather I sat in a chair with the back inclined at a suitable angle; but on cold frosty nights I found it convenient to maintain a standing posture, and sometimes to pace to and fro, always however keeping the eyes directed towards the firmament in quest of meteors."

Denning's papers on meteors were many, and touch the subject at many points. Bare mention can only be made here of stationary radiants, a difficult subject depending largely on his observations as data. Almost the last of these papers was one in November 1923, which is a catalogue of 314 radiants from observations made at Bristol between the years 1912 and 1922, and, with those in three previous lists of which this is a continuation, brings the total of radiant points determined by him to nearly 1500. The number of meteors observed by him in the years specified was 6220, and of these the flights of 4008 were recorded. This paper contains some notes embodying items from his experience or his views on various meteoric subjects that make it valuable. A General Catalogue of more than 4000 radiant points determined by himself and others, compiled by him, is to be found in vol. 53 of the Memoirs of the Royal Astronomical Society.

Besides the large amount of naked-eye observing here indicated, Denning found time to use his telescope, and in this respect his success was noteworthy. The search for comets is a task requiring assiduity and patience, and he was rewarded for efforts of this kind by the discovery of five. His first was on October 4, 1881, and the comet then discovered, after being further observed by himself and others, was believed to be periodic, but was, however, not seen afterwards. Comets discovered by him in 1890, 1891, and 1892 were not periodic, whereas for the fifth, discovered in 1894, a period of 7·3 years was computed. Many nebulæ not previously known were found by him in the course of his search for comets, and the Nova in Cygnus of August 1920 is credited to him as its first observer.

It is difficult to summarise or comment on Denning's observations of Jupiter and the other planets, but they comprise many determinations of rotation period of the giant planet from observation of various spots. He gave to the world his knowledge so gained in a book, "Telescopic Work for Starlight Evenings", published in 1890; and a brochure on the planets Mercury and Venus, a reprint of chapters contributed to the *Observatory* magazine, is a valuable summary of experience. In 1895 the Valz prize of the Paris Academy was awarded to him for his meteoric work, and in 1898 Denning was the recipient of the gold medal of the Royal Astronomical Society, the grounds for the award being his meteoric observations, his cometary discoveries, and other astronomical work. He received the degree of M.Sc. from the University of Bristol in 1927 *honoris causa.* In the year 1904 he was granted a Civil List pension of £150 a year for his services to science, for he followed no profession. In his youth he had worked with his father, who was Borough Accountant of Bristol, and it is somewhat unexpected to learn that at that time he was a cricketer of skill and reputation, and that he might have been included in the eleven representing his famous county. But he preferred a secluded life that he could devote to astronomy. Though not inclined to make friends personally, he had a large list of correspondents, whom he was always ready to help with advice, and one passes from among us who lived solely for the acquisition of abstract knowledge, for which he endured much self-sacrifice and sought no personal reward.

H. P. H.

WE regret to announce the following deaths:

Prof. Solon Irving Bailey, emeritus professor of astronomy in Harvard University, on June 5, aged seventy-six years.

Prof. Friedrich Becke, formerly general secretary of the Vienna Academy of Sciences, on June 18, aged seventy-six years.

Sir Hugh Bell, Bart, chairman of the council of Armstrong College, Newcastle-on-Tyne, and past-president of the Iron and Steel Institute, who occupied a prominent place in the industrial life of the north of England, on June 29, aged eighty-seven years.

Mr. E. W. Blair, senior scientific officer of the Royal Naval Cordite Factory, Holton Heath, who was killed in the explosion at the factory on June 23.

Dr. T. F. Chipp, assistant director of the Royal Botanic Gardens, Kew, on June 28.

News and Views.

IN our Supplement of this week will be found the main part of Sir Richard Glazebrook's Guthrie lecture to the Physical Society of London. The lecture was founded to perpetuate the name of Frederick Guthrie, the physicist through whose action in 1873 the Society was formed. Born in Bayswater in 1833, Guthrie studied chemistry under Graham and Williamson at University College, London, and also under Bunsen at Heidelberg and Kolbe at Marburg. Returning to England, he held posts at Owens College, Manchester, and the University of Edinburgh, and from 1861 until 1867 was professor of chemistry and physics in the Royal College, Mauritius, where he had as a colleague Walter Besant, the novelist. In 1869 he became a lecturer in physics at the Royal School of Mines and the Normal School of Science, South Kensington, and this post he held until his death on Oct. 21, 1886. John Hall Gladstone (1827–1902) became the first president of the new society, and Guthrie occupied that position in 1884. Unlike Guthrie, who was a chemist first and a physicist afterwards, Sir Richard Glazebrook has devoted all his life to physics. Born in 1854, after graduating at Cambridge he became one of the first demonstrators under Maxwell in the Cavendish Laboratory, and held other posts in the University. His main work has been done in the National Physical Laboratory, of which he became the first director in 1899. During his period of office, which lasted twenty years, he saw the staff increase from three persons to more than five hundred, and under him the Laboratory came to fulfil its object, " to make the forces of science available to the nation ".

To Sir Richard Glazebrook the subject of standards has been a lifelong study, and his Guthrie lecture is a valuable and authoritative review of the ancient standards, the connexion between ancient and modern standards, and the scientific methods by which the latter are examined, compared, and reproduced. As in so many other matters, the first application of science to the question of the weights and measures of Great Britain was due to the Royal Society, while the replacement of the old French measures by the metric system was due to members of the Paris Academy of Sciences. Graham, Bird, Troughton, Kater, Baily, Sheepshanks, and Miller were among those who introduced accuracy into British standards, while the history of the metric system is connected with such famous names as those of Lagrange, Laplace, Borda, and Condorcet. Not the least interesting part of Sir Richard's lecture is that dealing with the modern methods of basing standards on the length of the seconds pendulum, the quadrant of the earth, or the wave-length of light.

THE annual inspection of the National Physical Laboratory by the general board, on June 23, was made this year the occasion for the official opening of the new physics building by the president of the Royal Society, Sir Gowland Hopkins. Sir Richard Glazebrook, the first director of the Laboratory, and Sir J. J. Thomson, Master of Trinity College, Cambridge, and chairman of the research committee of the Laboratory, also took part in the ceremony. In the course of a brief sketch of the history of the laboratory since its formal opening in Bushy House in 1902 by the then Prince of Wales, Sir Richard Glazebrook referred to the early difficulties of the Royal Society in finding a suitable site for the laboratory. Sir Richard traced the development of the laboratory during the time that he was director and later, when he was succeeded by Sir Joseph Petavel; and he contrasted the space allotted to physics in the early days with that now necessary to meet the requirements of the physics department. A warm tribute was paid to the interest and insight of the many eminent men of science and engineers who have made possible the continued development of the laboratory.

SIR J. J. THOMSON in a brief speech pointed out that the choice of the Bushy Park site has been more than justified, on account of the tremendous expansion which has taken place since the laboratory was first formed. Sir Joseph referred to the place of the laboratory in the general development of pure and applied science, and to its relation to university and industrial laboratories. At the conclusion of the addresses, the new building was formally declared open by Sir Gowland Hopkins, and those present were afforded an opportunity of inspecting it. The design for the new building was prepared by Mr. F. A. Llewellyn, of H.M. Office of Works. The proposed building has a frontage of 295 feet with wings of 135 feet in length, forming three sides of a rectangle. The central portion only, with a frontage of 180 feet, has been erected at present, and will be used to accommodate the heat and general physics section of the physics department, with part of the radiology and sound divisions.

ON June 24, H.M. the Queen opened the Tuke Building at Bedford College for Women (University of London). The new building, the foundation-stone of which was laid by H.R.H. Princess Mary, completes a quadrangle and is dignified and stately, if rather severe in outline. The total cost of the building will probably exceed £110,000, of which a little more than three-quarters has been raised by grants and donations. Among its features are a fine lecture hall capable of seating the entire student body of the College, new laboratories for physical and inorganic chemistry, experimental psychology, and physics, besides accommodation for other departments, including philosophy and mathematics. Perhaps the most attractive feature of the new extension, for those interested in science, is the astronomical observatory, containing a seven-inch refracting equatorial by Grubb, generously presented by the Woolwich Arsenal Institution. The Department of Psychology occupies the first floor of one wing and comprises a lecture room and laboratories. The latter are well equipped with modern recording apparatus and material for studying the special senses. A pendulum tachistoscope is built into one of the walls. There is also a kodascope for the projection of films in the study of evidence and report. Special features of the new chemical laboratories are the replacement of gas heating by electrical devices—we hope that the bunsen burner, that symbol of the nineteenth century laboratory, has not vanished completely—and the arrangements for lighting and ventilation. The name of the new building commemorates the long principalship (1907–29) of Miss Margaret Tuke, who contributed so much to the success and present position of the College.

THE Repton School Science Society was founded in 1866 and has had an almost unbroken existence since that date. Among the original members of the Society are numbered Prof. F. O. Bower and Sir Martin Conway, M.P., and the records of the earliest meetings are interesting in that they show that the subjects discussed have now become part of the routine science teaching in the school. The Society held a conversazione at Speech Day, June 26 and 27, which consisted of short lectures, demonstrations, and exhibits in physics, chemistry, and biology. The physics section included, among other things, a lecture on X-rays, in which members of the audience were 'screened' to show the heart beating and the bones of the arm; there was also a lecture on the electrical gramophone, illustrated by records kindly lent by the Bell Telephone Laboratories, New York. The demonstrations included the principle of the Radiovisor burglary alarm, and a model to show the effect of coal dust on explosions in mines. There were lectures on dyes and liquid air in the chemistry section, and among the demonstrations were a set of experiments to illustrate bleaching and a group of experiments on electroplating. A notable feature of this section was a model of a petroleum refinery, lent by the British Petroleum Company. The biology section contained numerous dissections and exhibits, a micro-film of simple unicellular organisms actually taken by members of the Society, and a demonstration of blood circulating in the tail of an anæsthetised tadpole. Living chick embryos in various stages of development were also shown.

NINETY-FIVE heads and skulls of Asiatic and American ungulates and carnivores have been selected for the British Museum (Natural History) from the collection of the late C. St. George Littledale, and form the most important addition to the collection of Asiatic ungulates since the Hume bequest came to the Museum in 1912. The Zoological Department of the Museum has purchased a specimen of the pigmy hippopotamus from the French Ivory Coast. This animal is confined to a comparatively small area of West Africa, and does not seem to extend into the great forest zone of the Congo. The New York Zoological Society has presented to the Museum a skeleton of the extinct giant tortoise of Charles Island, Galapagos. In 1832 the island was colonised, and within a short time the animals were exterminated. There was considerable doubt as to the exact species until a large number of complete skeletons, of which the present specimen is one, was discovered in a cave by Dr. C. H. Townsend in 1928. The collections brought home by Mr. Bertram Thomas from the Rub'al Khali, Arabia, are now being worked out, and a selection has been placed on exhibition in the Central Hall of the Museum. The mammals include two foxes of interest, an Arabian race of the common fox, and a fennec fox. The reptiles of the desert region are chiefly Asiatic in their relationships, whereas the affinities of those of the Qara Mountain region are with the reptiles of East and North-East Africa. The insects demonstrate very clearly the strong affinity existing between the fauna of southern Arabia and Africa. Many species have not been observed hitherto outside Africa; there is also a marked Mediterranean element. Recent acquisitions in the Mineral Department include two small diamonds, the first found in Sierra Leone; a piece of an unusual type of stony meteorite which was seen to fall on Nov. 25, 1930, at Karoonda, South Australia (see NATURE, Mar. 14 and April 25); and a mass of meteoric iron weighing 125 lb., found in 1922 at Piedade do Bagre, Minas Geraes, Brazil, which is a single crystal individual.

IN an interesting letter to the *Times* for June 16, the Rev. J. P. Rowland, *S.J.*, has estimated the position of the epicentre of the North Sea earthquake of June 7. From the times of the first and second phases on the Kew and Stonyhurst records, he finds the time at the origin to be 0 h. 25 m. 12 s. G.M.T. From this and the time of arrival at six British observatories, the distances of the origin from the various observatories were calculated and arcs of circles were drawn on the map with the stations and distances as centres and radii. The point in which the arcs for Kew and Stonyhurst intersect is adopted as the epicentre, namely, 53° 43·8′ N., 0° 53·2′ E. The arcs from the other stations, with the exception of Oxford, form a small triangle at distances of not more than two miles from this point. According to the *Daily Science News Bulletin* (June 8), issued by Science Service, Washington, D.C., the earthquake had but little effect on the seismographs in the United States. It was recorded at Washington and rather indefinitely at Georgetown University.

CONTINUOUS daily records of the hours of bright sunshine have been made by many of the meteorological stations in all parts of the world for many years, and these records have proved useful in various lines of scientific research. In one of the usual methods, a record is burned on a card by the solar rays concentrated by a glass sphere. Provided the instructions given with the instrument are carefully followed, this method gives fair results. Difficulties arise in interpreting the results on a day when the sun has been intermittently obscured by numerous small but dense cumulus clouds. The burned spots have to be considered collectively, and the estimate made of the total hours is only a rough approximation. In the *Canadian Journal of Research* for March 1931, Wallace A. Thomson describes a method of recording the bright sunshine by means of a photoelectric cell and an electric clock. When light of a definite intensity falls upon the photoelectric cell, the electric clock is automatically started by the action of a relay. This relay also stops the clock just as promptly when the sun disappears behind a cloud or below the horizon. It is thus only necessary to read the time on the clock at the end of each day, when the number of hours it has been running since it was last observed gives the number of hours of sunshine during that period of time. Comparative records are given of the hours of bright sunshine observed during a week at Manitoba Agricultural College by the author's cell and clock, by two types of sunshine recorder, and by personal observations by the author. It was found that the photo-cell and clock method never omitted any portion of the daily record that would not be considered questionable. On several days, the clock continued to operate until only half the sun was visible above the horizon. The other methods sometimes omitted about two hours of the record.

STRIKING progress continues to be made by the recently formed industry for canning English-grown fruits and vegetables. During the last two years, the number of firms in operation has risen from five to nearly forty, and the output has increased fourfold since 1928. The application of the National Mark Scheme in 1930 considerably stimulated the demand for English canned products, and although during this first season the scheme was applied to some half-dozen fruits and vegetables only, yet more than fifty per cent of the total output (which equalled the total imports of canned fruits other than pineapples from the rest of the Empire) was packed under the mark. Further, the high standard of quality required was well maintained. Encouraged by this success, the Ministry of Agriculture states in a recent weekly news-sheet that it is now extending the scheme to a much larger number of fruits and vegetables. Careful attention is also being paid to standardisation, particularly as regards sizes of cans, weight of fruit, and strength of syrup. Four sizes of cans will be put on the market, and two different strengths of syrup will be available. Lacquered cans, although already widely employed, will be required for red and blue fruits and for peas and beans sold under the National Mark Scheme. A large market for English canned produce is available in the Empire, particularly in South and East Africa and in India, several consignments having already been dispatched, but careful co-operation between the fruit and vegetable growers and the canner is necessary, if full advantage is to be taken of this rapidly expanding market.

THE most striking feature of the National electricity scheme in Great Britain is the grid, the common distribution mains of all the selected power stations. This makes necessary the standardisation of all systems of supply, and to effect this many difficulties have to be overcome. The principal difficulty is the standardisation of the frequency of the alternating current supplied by the various companies. The cost of this work was not over-estimated when it was put at eighteen million pounds, but it is defrayed by the Central Electricity Board in the first instance and will afterwards be recovered by a levy on the whole of the electricity supply undertakings in the country. There are three main areas affected. In central Scotland the Glasgow Corporation and the Clyde Valley Co. are changing over from 25 cycles to 50 cycles. A similar change is being made in Birmingham. The operation has to be done gradually, as provision must be made for the continued use of consumers' machinery during the change. The most difficult problem of all is the conversion of the north-east England scheme, where the greater part of an area of over five thousand square miles is supplied at a frequency of 40·8 cycles per second. A change of frequency affects every piece of rotating apparatus, from the power house to the smallest domestic motor. All electromagnetic devices are more or less affected. In making new installations it is necessary to erect machines which can work at dual frequency or, at least, which can readily be converted from one to the other. As the Electricity Board points out, this change gives an opportunity to many important industrial works of economically modernising and re-equipping their electrical machinery. Many ways of doing this are described in the *English Electric Journal* for June.

THE keen competition that is taking place for overseas traffic makes it necessary for marine engineers to keep abreast of the latest engineering developments. The expenditure of several millions on a new liner is only justified if it remain an efficient unit for at least twenty years. Too slavish an adherence to the policy of 'safety first' may lead to it being outclassed by a competing vessel. In the *Electrical Times* for June 4, A. D. Constable discusses fairly fully the case for the use of electric propulsion in a large high-speed liner. A detailed scheme is worked out, and he advocates notable innovations in marine engineering practice. At first sight a direct mechanical drive between the turbines and the propeller shaft seems more desirable than to install electric generators and motors between them, especially as the transmission losses in the case of large liners are about six per cent less for the mechanical drive. The cost of the electrical machinery is also the greater. On the other hand, the great flexibility of the electric drive, the possibility of using five propeller shafts and twin rudders, the economical working at all speeds, and the great convenience of having all the auxiliary services on board ship worked electrically, in many cases indicate that the all-electric ship is the more economical. Provided that every electrical machine and device is of the best materials and design and in accordance with the most modern specifications, the ship should run in all weathers with freedom from trouble and anxiety, and with an economy hitherto not reached in marine work. If in addition higher steam pressures were used in the boilers, a very appreciable reduction might be made in the excessive amount of space now occupied by the boilers.

THE annual report of the Director of the Imperial Institute, Lieut.-Gen. Sir William Furse, shows

Standards of Measurement: Their History and Development.*

By Sir RICHARD GLAZEBROOK, K.C.B., F.R.S.

ANCIENT STANDARDS OF LENGTH.

WHEN man became a measuring animal, he naturally took as his standards the parts of his own body. The cubit, the length of the forearm from the elbow joint to the tip of the middle finger, was his unit of measurement; the Egyptian hieroglyph for a cubit is a figure of the arm, and this unit was divided into spans, palms, digits, etc. There were various cubits, differing somewhat in length, and our knowledge of them has come to us in the main from Egyptian monuments. It appears probable, however, that the Egyptians obtained their cubit originally from Chaldæa, and one of the oldest standards we know of is to be found in the Louvre, where there is a bust of Gudea, a Sumerian king of about 2300 B.C. On it there is engraved a scale showing sixteen digits of the Sumerian cubit, which was divided into thirty digits.

The cubit from which it appears probable that our foot and inch have descended is generally known as the Olympic cubit, because it passed from Egypt into Greece. It was, as we shall see shortly, about 18·24 in. long and was divided into two spans, the stretch from the thumb to the little finger, of about 9 in. A span was equal to three palms, the breadth of four fingers, each being about 3 in. in length, and the palm was divided into four digits, each ¾ in., or more accurately 0·76 in. There was also the fathom of 4 cubits, 72·96 in. or 6·08 ft., the outstretch of the two arms.

At a somewhat later date another unit, the foot, equal to two-thirds of a cubit, was introduced, and this was divided into twelve thumb-nail breadths—Gk. ὄνυξ—whence came the terms uncia, ounce, inch, used for the twelfth part of the troy pound and of the foot.

I have not heard of an existing specimen of an Olympic cubit, but we can determine its length in the following manner. Herodotus tells us that "the Egyptian cubit is equal to that of Samos", that is, the cubit used in Greece, and we can obtain the length of this from the measurement of various Greek temples. The Hecatompedon of the Parthenon is a square of 100 ft. in side. This was measured in 1846 by F. C. Penrose, who gave as the length of the Greek foot 12·1610 in.; whence the cubit, being 3/2 feet, is 18·2415 in.; this was corrected later to 18·2405 in., or (say) 18·24 in.

There is another link to be obtained thus. The side of the Great Pyramid is stated to be 500 cubits in length. This has been frequently measured. Sir Henry Lyons informs me that the result obtained a few years since by Mr. J. H. Cole, of the Egyptian Survey, was 230·364 metres or 755·76 ft. Earlier measures give much the same result. Sir Flinders Petrie found the average length to be 9068·8 inches or 755·7 ft., giving for the length of the cubit, if we accept the statement that a side of the base of the Pyramid measured 500 cubits, the value of 18·14 in. This is nearly the same as the 18·24 inches found from the Greek temple, and we may perhaps accept this value as close to the truth. This foot with its division into twelve thumb-breadths (ὄνυξ) became the Greek foot.

In due course, the foot passed to Rome, becoming somewhat altered in value; the Roman mile of 5000 Roman feet is generally said to be equal to 8 Greek stadia, each of 600 ft. or 400 cubits, so that the Roman foot was equal to 24/25 of the Greek foot, or 11·67 English inches. This makes the Roman foot equal to 0·973 English feet. Direct measurement by Martin Folkes and others give as the value 0·967 English feet, or putting it the other way round, 1 English foot = 1·03 Roman feet.

---

* From the Guthrie Lecture for 1931, delivered before the Physical Society of London on May 15. I wish to express my indebtedness to many friends, and first and foremost to Sir Henry Lyons, for most of the historical apparatus shown during the lecture, to the Deputy Warden of the Standards for apparatus in his charge, then to the Director of the National Physical Laboratory and Messrs Sears and Dye for their valued help, and to Mr. Chrislelow for his care in preparing the slides. For the part relating to ancient standards, thanks are due to Col. N. Belaiew, C.B., to Mr. Sidney Smith, of the British Museum, and to the library staff of the Royal Society, who helped in looking up the references; while I am indebted to Mr. Hope Jones, of the Synchronome Co., and to Mr. Shreeve, representing the Bell Telephone Co., for information as to time measurements.

In time, Roman measures were established in Britain, but as to when and how the change from the Roman to the British foot took place we have no evidence. Various surmises are possible. It is known that the Gothic nations in the fourth and fifth centuries, established in the neighbourhood of the Crimea, used a large cubit. This became the basis of the Russian measures prior to the reign of Peter the Great, and may have travelled westward with the Goths and been brought to England by the Anglo-Saxons. But more likely it was a chance alteration. Maybe King Henry I. did fix the yard by the outstretch of his arm, and this happened to give a foot some three per cent in excess of the Roman foot.

King David of Scotland (*c.* 1150) ordained that the Scotch inch should be the mean measure of the thumbs of three men, the thumbs being measured at the root of the nail. There was a standard foot fixed in Old St. Paul's and all measures were referred to the standard, "qui insculpitur super basem columpnae in Ecclesia Sancti Pauli".

In the time of Queen Elizabeth, steps were taken to fix definite standards of measurement, but before telling of these it is desirable to refer to the history of weights.

ANCIENT STANDARDS OF WEIGHT.

The standard of weight in Sumerian times was the mina, the history of which has been very fully examined by Col. Belaiew. From the mina in course of time came the talent, and the Alexandrian talent formed the basis of the Greek, Roman, and western European weights until the advent of the metric system.

The Alexandrian talent was divided by the Romans into 125 libræ, each containing 12 unciæ, so that there were 1500 ounces to the talent. The weight of the talent has been found to be 93·65 lb. avoirdupois or 655,550 grains. Thus the weight of the Roman ounce was 437 grains while the pound contained 5244 grains. This weight became current in Britain, but the pound, instead of remaining at 12 oz. was raised to 16 oz., each of 437 grains, and possibly became the basis of our avoirdupois weight, a pound of 6992 grains. Another suggestion is that the pound avoirdupois came from the Attic mina of 6945 grains.

The Saxon kings, however, had brought to England as a standard weight the marc of Cologne. Two marcs weighed 7216 grains and were divided into 16 oz. each of 451 grains. Twelve of these ounces, reckoned as weighing 450 grains each, constituted the Tower or Mint pound[1] by which the coinage was weighed. In the time of Edward III., a Tower pound of silver was coined into 240 silver pennies each weighing 22·5 grains, giving 5400 grains for the pound and 450 for the ounce.

There was another pound in ordinary use, the Troy pound. Its origin is uncertain. In France we find a Marc de Troyes of 472 grains to the ounce and it may have come from that. Another suggestion is that the word troy has no reference to the French town but rather to Troy Novant, a monkish name of London founded on the legend of Brutus. Troy weight was mentioned in the reign of Henry IV., and in the time of Henry V. goldsmiths were ordered to use "la libre de Troy" and coin 360 pennies from a pound of 5400 grains. Thus a penny weighed 22·5 grains, and an ounce 450 grains.

The troy pound became the standard for the coinage in 1527, when Henry VIII. enacted that "the pounde Towre shall be no more used, but all manner of golde and sylver shall be wayed by the pounde Troye which maketh XII. oz Troye and which excedith the pounde Towre by III. quarters of the ounce". This would make the pound troy weigh 5737·5 grains. It was afterwards defined as 5760 grains, and the ounce troy (1/12 part) as 480 grains.

Throughout this time avoirdupois weights, though not defined by statute until 1485, had been used, and from quite early days a Libra Mercatoria one-fourth greater than the Tower pound and containing therefore 6750 grains was employed.

In the time of Edward III. (1352) we read of weighings "cum ponderibus de haberdepase", and weights of this denomination existed in the time of Elizabeth. "Haberty poie" pound is mentioned in the time of Henry VII. Henry VIII. (1532) ordered that meat shall be sold by weight called Haver-du-pois.[2] The Avoirdupois pound contained 16 Roman ounces of 437 grains each—6992 to the pound.

Elizabeth by her action in 1574 introduced what has become our modern system of weights and measures. She ordered a jury to examine the standard weights and measures in use, to report on them, and to construct standards "as well of troy weight as of avoirdupois ". The existing standards were found to be very erroneous, and a second jury was appointed in 1584. The result of their work was the production of 57 sets of weights, both troy and avoirdupois, which were distributed to the Exchequer and various local authorities. Some of these weights are still extant, and do not differ by more than a grain from the Imperial standard.

---

[1] In 1842 a Tower pound from the Pyx Chamber was found to weigh 5404 grains.

[2] According to the "New English Dictionary", quoted by Nicolson, to whose book, "Men and Measures", I am indebted for much of this account of English weights, Averdepois is the best spelling of the name. *Aver* is an old-established English word for 'goods'.

Either at this period or previously the weight of the avoirdupois pound was raised by 8 grains, bringing it from 6992 to 7000 grains, at which it has remained ever since. Thus the avoirdupois ounce is 437·5 grains.

The Proclamation for Weights of Dec. 16, 1587, established avoirdupois weight, and ordered that no " person shall use any Troy weight but only for weighing of bread, gold, silver, and electuaries and for no other thing ".[3] In addition, standards of length and capacity were constructed; the standard yard of Elizabeth is continually referred to later and was an important factor in determining the length of our present standard. The work was well done, and supplied in a satisfactory manner the needs of the country for more than a hundred and fifty years.

THE PYRAMIDS AND THE CUBITS—EGYPTIAN STANDARDS.

Before continuing the history of these standards, it is of interest to go back to Egyptian times and to the Pyramids, and to learn more about those standards from which ours have undoubtedly come. I have based our foot on the common or Olympic cubit of 18·24 inches, but there were many other cubits. One in particular, the Royal cubit of Egypt, is closely connected with the building of the Great Pyramid.

John Greaves, Savilian professor of astronomy at Oxford in 1643–49, became professor of geometry in Gresham College, London, in 1631, and after some visits to the Continent started on a journey to the East in 1637. After visiting Rome and Constantinople, he arrived at Alexandria in 1638, and thence " he went twice to Grand Cairo to measure the Pyramids, carrying with him a Radius of ten feet, most accurately divided into 10,000 parts, besides some other instruments for the fuller discovery of the truth ".[4]

In his "Dissertation on Cubits", Newton sets down the dimensions given by Greaves for various parts of the Pyramid. He then argues, following Greaves, that the builder probably used a definite unit in the design of his work, and by comparing the figures endeavours to fix on that unit; the result is shown in the following table, in which are included the dimensions of two of the principal passages and of the great central chamber, as well as the length of one side of the great Pyramid.

TABLE OF GREAVES' MEASUREMENTS OF THE PYRAMIDS.

Part Measured.	Dimensions in Feet.	Value of Cubit deduced.
Breadth of entrance gallery .	3·463	2 × 1·732
Breadth of main gallery .	6·870	4 × 1·718
Height of side benches in main gallery . . .	1·717	1·717
Breadth of side benches in main gallery . . .	1·717	1·717
Length of central chamber .	34·380	20 × 1·719
Breadth of central chamber.	17·190	10 × 1·719
Length of north side of base .	693	400 × 1·732

The mean value for the cubit, excluding the first and last, Newton takes as 1·719 ft. The last line of the table, as will appear shortly, is clearly erroneous; as to the difference between the first line and the others, Newton remarks that it comes to about 1/7 in., which is " an error of no importance if we consider the much greater irregularities observed by Mr. Greaves in the best buildings of the Romans ".

As to the base measurement there is clearly some error; the true base was covered by debris until recently and could not have been measured by Greaves.

If we take Newton's value 1·719 ft. as the outcome of Greaves' measurements in 1638–39, we obtain as the length of the Royal cubit used in the interior of the Great Pyramid, 20·628 inches. There is ample evidence that a cubit of about this size was in general use. There is one in the British Museum, another in the Liverpool Museum, and a third in Paris. Mr. Nicolson mentions others.

The cubit is found also on the outside of the Great Pyramid; at each corner were vertical walls, used by the builder to set out the slope of the faces. Two of these are extant and are marked in cubits of this size. From this it would appear that the Royal cubit was used throughout the building. Moreover, there still exist a number of Nilometers, used in ancient times to measure the height of the Nile flood along the valley. These are marked in cubits. Several of them were measured by Sir

[3] Nicolson, " Men and Measures," p. 102.

[4] The life of Mr. John Greaves, by Thos. Birch, Sec. R.S., prefixed to the miscellaneous works of Mr. John Greaves, Professor of Astronomy in the University of Oxford. Published by Thos. Birch, F.R.S., 1737.

Henry Lyons and Dr. Borchardt when in Egypt, with the following results :

Nilometer.	No. of Cubit Lengths.	Average Cubit in Metres.
Philae I.	12	0·520
Philae II.	12	0·532
Philae III.	16	0·535
Elephantine	12	0·523
Edfu	6	0·528
Esna	9	0·532
Luxor	6	0·529

The mean of these is 0·528 metre or 20·8 inches. Other measurements have given a rather less result.

The mean value found by Mr. Cole for the length of the side of the base was 755·8 feet. If this is to contain an even number of cubits of about the length found otherwise for the Royal cubit, that number will be 440. Assuming this as the number of cubits in a side, the length of the cubit is 1·718 ft. or 20·62 in.

The following give the lengths of the four sides of the base as measured by Sir Flinders Petrie and Mr. J. H. Cole:

	Sir Flinders Petrie.	Mr. J. H. Cole.
North	755 ft. 9 in.	755 ft. 5 in.
East	755 ft. 8 in.	756 ft. 1 in.
South	755 ft. 9 in.	755 ft. 11 in.
West	755 ft. 9 in.	755 ft. 10 in.
Mean	755 ft. 8·7 in.	755 ft. 10 in.

The agreement is practically complete.

Thus we have found good cause to suppose that there were two cubits in general use—there were others besides—one 18·24 inches in length, the other 20·62 inches. It is, perhaps, natural to inquire what was the reason for this, and Col. Belaiew pointed out to me a fact of interest in this connexion.

We know if we call l and L the lengths of the two, we have

$$\frac{l}{L}=\frac{18{\cdot}24}{20{\cdot}62}=0{\cdot}885=\tfrac{1}{2}\sqrt{\pi}\text{ approximately.}$$

Thus $l^2=\tfrac{1}{4}\pi L^2$.

Hence the area of a square having the small cubit for a side is equal to that of a circle with the large cubit for its diameter. This may, of course, be chance or it may be that some ancient Egyptian, wishing to construct a circle of the same area as the square, found the large cubit. We know that the value 256/81 was used for π, so that $\sqrt{\pi}=16/9$.

There are other curious facts connected with the dimensions of the Great Pyramid. Its perimeter, following Mr. Cole, is $4\times755{\cdot}8$ or 3023·2 ft. Earlier measurements made the base 760 ft. in length and the perimeter 3040 ft. Now the mean length of a nautical—meridian—mile, the sixtieth part of a degree, is 6080 ft. Thus the perimeter of the Pyramid is very approximately half a meridian mile. Did the wise men of old know this, and were they aware that the earth is spherical and about 8000 miles in diameter ? If the perimeter of the Pyramid was 2000 Olympic cubits, then the Olympic cubit is 1/4000 of a meridian mile and the Olympic fathom—the Greek *orgia* of 4 cubits—is one sixty-thousandth of a degree.

It is all very curious ; but can we credit such knowledge to the men who designed the Pyramids ? They placed them very accurately with regard to the meridian ; the faces of the Great Pyramid are only 3′ 43″ out, while the entrance gallery was directed towards α Draconis, the Pole Star some 5000 years ago. Thales of Miletus, born 640 B.C., taught that the earth was spherical and placed it at the centre of the universe. Pythagoras, born 580 B.C., said that the sun was the centre of the planetary world and the earth one of the planets.

THE ALEXANDRIAN TALENT.

In connexion with the weights, equally interesting questions arise when one begins to ask, How did men in ancient days settle on their system of weighing ? Their standards of length represented, without doubt, the lengths of parts of their own bodies; their weights may well have been chosen to represent a definite quantity of some commodity in daily use —wheat or barley, the weight and length of the grain of which has been in all countries intimately connected with standards of weight and length. The kilogramme was intended to be the weight of a unit of volume of water. How far back does this idea go ? We have seen that the Alexandrian talent weighed 93·65 lb. A simple calculation shows that the weight of a Royal cubic foot of water is 2594/27·71 lb. or 93·61 lb. Is it a coincidence that the weight of the talent of Alexandria is so closely that of a Royal cubic foot of water, or is the suggestion made by Mr. Nicolson that the agreement was designed, correct ?

THE FOOT AND THE OUNCE.

Here it is perhaps relevant to refer to another suggestion made by Mr. Nicolson in an endeavour to account for the difference between the Olympic and the British foot. It is that the foot was chosen so as to make a cubic foot of water weigh 1000 ounces of (at the time) 437 grains each. This will be found to be very closely the case. But I am digressing into curiosities of metrology. The weight of a cubic foot of water was investigated by the Oxford Philosophical Society in 1685. When Wren and the founders of the Royal Society moved to London, those of the members left behind at Oxford continued their meetings,[5] and at one of these, two members, Messrs. Caswell and Walker, described how they had made a hollow cube of very hard dry oak, each edge of which was very exactly one foot, with which they proposed to determine the weight of a cubic foot of water. At a later meeting they communicated their result to the Society, finding it to be 1000 oz., and their result, along with the weights found for the same volume of a number of other substances, was sent to the Royal Society and is printed in the *Philosophical Transactions*[6] along with their table of specific gravities.

This has brought us very close to what I may perhaps call the more scientific period of our subject, and we may leave the speculations, interesting though they are, that centre round the Pyramids and their architects.

THE ROYAL SOCIETY AND WEIGHTS AND MEASURES.

We come now to more modern times, some two hundred years ago, and from that date onwards we can trace with more certainty the history of our weights and measures.

In 1742, George II. was on the throne; the Royal Society had been founded for nearly eighty years and its fellows were actively engaged in the pursuit of natural knowledge; the importance of exact measurement was becoming more fully recognised. Vol. 42 of the *Transactions* for 1742–43 contains the account of various comparisons of weights and measures. In it is also described the laying down of 3 ft. on a brass bar belonging to the Royal Society from a scale at the Tower.

Owing mainly to the action of Graham, sundry comparisons with French and other measures were made, and with this object he had two yard measures and two pound weights carefully made and examined. One of each of these was sent to Paris by the Society and, at the request of the French men of science, were compared with the French standards by M. du Fay and the Abbé Nollet. This seems to have led to the suggestion that a formal comparison of the existing standards of length and weight was desirable, and a committee, under the chairmanship of Lord Macclesfield, undertook the task and reported on June 16, 1743.

Among the standards compared were those included in the following table :

Comparisons of Yards with the Exchequer Standard of Elizabeth.	
Royal Society yard	+ 0·0075 in.
Henry VII. yard	− 0·0071 in.
Guildhall yard	+ 0·0434 to 0·0396 in.
Clockworkers' yard	− 0·021 in.
Tower yard	+ 0·011 in.

The committee also examined a series of weights from the Exchequer and elsewhere.

From the time of Edward I., the troy pound is defined as containing 12 troy ounces each of twenty pennyweight; but no standard troy pound was found; 12 ounces taken from a box containing 256 ounce weights were therefore selected as representing the pound troy.

There was, however, a series of avoirdupois weights, from 1 lb. to 14 lb., marked Elizabeth Regina 1582, and a 7 lb. wt. VI. Ed. 1588. Various comparisons led to the following results for the lb. and oz. avoirdupois in grains :

Pound . . .	6998	7000·7	7000·2
Ounce . . .	437·4	437·54	437·51

Of the weights in the possession of the Royal Society, the avoirdupois pound was lighter than the standard by one grain, and the troy pound lighter by half a grain. This constitutes the earliest systematic comparison of our weights and measures that I have found.

It was realised that the length of the standards varied with temperature, but it was held that since all were of much the same material the differences would not be affected.

Two standard bars were made by Bird in 1758 and 1760 respectively for a committee appointed by the House of Commons under the chairmanship of Lord Carysfort. These were to be copies of the Royal Society standard as laid down by Graham, 1742–43. One, marked Standard Yard 1758, was presented to the House as the legal standard of length. Both were compared in 1768 with the Royal Society standard, while in 1785 a scale made for General Roy's measurement of an arc of the meridian on Hounslow Heath was graduated in terms of the same standard. Bills were presented to the House of Commons in 1765 to give effect to the recommendations of this and of a subsequent committee, but from some accident they did not become law and the country remained without legal standards for the next sixty years.

The modern method, employing micrometer microscopes, was used for the first time by Troughton in his comparison of a line standard constructed

---

[5] Their Minute Book is now at the Royal Society, and from it these notes are taken.

[6] *Phil. Trans.*, No. 169, p 926, Mar. 23, 1685.

P20571

in 1792 for Sir George Shuckburgh. In 1814 a report was presented to the House of Commons by a new committee which asked Dr. Hyde Wollaston and Prof. Playfair for advice. They stated that the length of the pendulum vibrating seconds had been found to be 39·13047 in. and that the metre of platina measured, at the temperature of 55°, 39·3828 English inches, representing at 32° the ten-millionth part of the quadrant of the meridian. They recommended, upon the suggestion of Dr. Wollaston, "that a gallon containing ten pounds of pure water should be adopted as a substitute for the ale and corn gallons".

In 1816 there still remained considerable doubt both as to the length of the seconds pendulum and the relation of the metre to the inch; the Astronomer Royal, Dr. Pond, was instructed by Parliament to make the measurements necessary to remove the doubt. He asked for the assistance of the Royal Society, and a committee was appointed for the purpose.

A number of experiments were made by various methods (Capt. Kater's pendulum work is described in the *Phil. Trans.* for 1826, 1830, and 1831), and in 1818 a Commission was appointed, under writ of the Privy Seal, "to discuss the matter more minutely than could be done with convenience before a Committee of either House of Parliament".

The report of this Commission drawn up by Dr. Young is of great interest; and as a result a Bill giving effect to their conclusions was brought into the House of Commons by Sir George Clerk in 1822, and again, with a few amendments, in 1823. This was nearly identical with an Act passed on June 17, 1824, which came into force on Jan. 1, 1826.

The Commissioners ultimately recommended for the legal determination of the standard yard Bird's standard of 1760. It was found to agree very closely with Sir George Shuckburgh's yard, with which the length of the pendulum and the metre had been compared, and a facsimile of which was known to exist at Geneva, and the Act enacted "that the straight line or distance between the centre of the two points in the gold studs in the straight brass rod now in the custody of the Clerk to the House of Commons whereon the words and figures Standard Yard 1760 are engraved shall be and the same is hereby declared to be the original and genuine standard of that measure of length or linear dimension called a yard". The distance when the rod was at a temperature of 62° Fah. was denominated the Imperial Standard Yard, and all other measures of extension were to be multiples or sub-multiples of this standard.

For the standard of weight the Commissioners recommended in 1823: "That the Standard brass weight of one pound Troy weight in the year 1758 now in the custody of the Clerk of the House of Commons shall be, and the same is hereby declared to be the original and genuine standard of weight; and that such brass weight shall be and is hereby denominated the Imperial Standard Troy Pound". This troy pound was declared to contain 5760 grains, "and 7000 such grains shall be and are hereby declared to be a pound Avoirdupois".

For the recovery of the standards if lost, destroyed, defaced, or otherwise injured, suitable provision was made in the Act; the yard was to be recovered from the length of the seconds pendulum, which when vibrating in a vacuum at sea level in the latitude of London was stated to be 39·1393 in., while it was held that the pound could be reconstructed from the fact that a cubic inch of distilled water weighed by brass weights in a vacuum at a temperature of 62° had been found to weigh 252·724 grains.

THE MODERN STANDARDS.

The need for reconstruction came all too soon. In 1834 the Houses of Parliament were destroyed by fire; the pound standard was lost entirely, the yard standard was damaged, one of the gold plugs having been melted so that its centre point could no longer be determined with accuracy.

In 1838 the Chancellor of the Exchequer, the Right Hon. T. Spring Rice, set up a Commission to advise as to the steps necessary to replace the standards.

Meanwhile, since 1824 a number of criticisms of the means suggested for recovering the standards had been made. Certain of the corrections employed by Kater in determining the length of the seconds pendulum were shown to be in error; while the agreement among the various determinations of the weight of a cubic inch of water left the true value in doubt, and the committee of 1838, accepting these criticisms, threw over the methods provided in the Act of 1824 and advised, with regard to the pound, that it should be recovered by comparison with copies which were known to exist and that the pound avoirdupois should be the standard. As to the yard, it was stated that "Several measures now exist which were most accurately compared with the Standard yard . . . and by the use of these the values of the original standards can be respectively restored without sensible error". The committee, therefore, recommended a material standard, "the distance between two points or lines engraved on metal, but that the standard be in no way defined by reference to any natural basis, such as the length of a degree of a meridian on the earth's surface in an assigned latitude or the length of a pendulum vibrating seconds in a given place ".

The Government approved this recommendation and appointed a scientific committee in 1843 to reconstruct new Parliamentary standards of length and weight.

THE POUND.

Prof. Miller was entrusted with the construction of the pound, Mr. Baily with that of the yard. Prof. Miller has described his work very fully in a Royal Society paper.[7] The standard weight of 1824, made of platinum, was known as *U*. It had been compared in 1824–25 by Capt. Kater with five gun-metal standards deposited at the Exchequer, the Royal Mint, and with the civic authorities in London, Edinburgh, and Dublin.

In 1829, *U* had been compared by Capt. V. Nehus with a platinum pound (*R.S.*) belonging to the Royal Society, and also with two brass pounds and a platinum pound (*Sp.*) in the custody of Prof. Schumacher. These weights, with a number of gun-metal copies, were available for the construction of the new pound. The comparison showed considerable discrepancies in the values of the gun-metal and brass weights, and in the end it was resolved, " with the consent of the Astronomer Royal, to rest for the evidence of the weight of the lost Standard entirely on the comparisons of the two platinum Standards *Sp.* and *R.S.*"

As the result of this work, and the corresponding work on the yard, our present standards came into existence, and the Weights and Measures Act of 1855 prescribes that:

" Whereas by Act of the Fifth Year of King George IV. a standard brass weight of one pound troy, made in the year 1758, then in the custody of the Clerk of the House of Commons, should be the genuine standard of weight, and whereas there exist weights which had been accurately compared with the said Standard Pound Troy which afforded sufficient means for restoring such original Standard:

" The said weight of Platinum marked P.S. 1844 1 lb. deposited in the Office of the Exchequer as aforesaid shall be and be denominated the Imperial Standard Pound Avoirdupois. The one 7000th part of this shall be a grain and 5760 such grains shall be a Pound Troy."

Provision is made in the Act for recovery of the standard if lost by comparison with copies made and distributed among various authorities. Thus the pound avoirdupois became our standard of weight, and the pound troy followed in the path of the King's Tower pound.

THE YARD.

Mr. Baily, at the request of the committee, undertook the reconstruction of the yard. The account[8] of the work is given by Sir George Airy as chairman in a paper in the *Philosophical Transactions* of the Royal Society.

In addition to the damaged standard, the following were available for comparison: a scale, No. 46, belonging to the Royal Society, a scale belonging to the Royal Astronomical Society, two three-foot bars of the Ordnance Society. There was also the Shuckburgh scale of 1792, but on account of certain imperfections little importance was attached to it.

The standard was to be of bell metal or steel, a rectangular bar of about 1 in. square in section, with the ends notched away to half the thickness. The marks defining the length were to be on plugs inserted flush with the surface, and the standard was to be correct at 61° or 62° F. The ends were cut away in order that the marks might be in the median plane of the bar and the effect of flexure when supported at two points minimised. For the standard finally settled on, an alloy, since known as Baily's metal, consisting of copper 16 parts, tin $2\frac{1}{2}$ parts, and zinc 1 part, was used.

Faraday was consulted somewhat later as to the stability of such an alloy, and wrote: " I do not see why a pure metal should be particularly free from internal changes. . . . I suppose the labour would be too great to lay down the standard on different metals and substances, and yet the comparison of these might be very important hereafter, for twenty years do seem to do or tell a great deal in relation to standard measures."

Baily also introduced the method of drilling a hole in the bar down to the median section, and fixing the plug with the mark at the bottom of this instead of notching the end as Kater had done. His work was cut short by his death in August 1844.

At this stage, Sheepshanks offered to take Baily's place, and the question immediately before the committee was whether to attempt to restore the damaged legal standard or to construct a standard from the available material. It was plain that in the strictly legal or scientific sense the restoration of the standard must be indefinite and the latter plan was approved. Sheepshanks suggested that the necessary apparatus for his comparisons should be set up in the cellar of Somerset House, and made a report on the questions involved, the stability of the material, the thermometric difficulties, etc., as well as on the method he proposed to adopt.

---

[7] On the Construction of the New Imperial Standard Pound by Prof. W. H. Miller, *Phil. Trans.*, 1856.

[8] Account of the Construction of the New National Standard of Length by G. B. Airy, Esq., Astronomer Royal, *Phil. Trans.*, 1857.

A meeting of the committee was held on June 4, 1847, to inspect these arrangements, and the minutes record that—

"The Committee approve entirely of the course followed by Mr. Sheepshanks and request Mr. Airy to take measures for the exam^n and discharge of the instrument makers accounts."

Airy's paper already referred to gives very full details of the construction of the standards; it also contains his investigation of the effect of flexure and the determination of best points of support.

Ultimately, six standards of Baily's metal were constructed which were found to have the length of 1 yard at the temperatures indicated below:

No. 1.	. . .	Correct at 62° F.
2.	. . .	" " 61·94 F.
2.	. . .	" " 62·10 F.
4.	. . .	" " 61·98 F.
5.	. . .	" " 62·16 F.
6.	. . .	" " 62·0 F.

Of these, it was arranged that No. 1 should become the standard yard, while 2, 3, 4, and 5 should be known as Parliamentary copies, and No. 6 should be retained by some officer of the Government for the comparison of other standard bars or for other scientific purposes.

Sheepshanks was taken ill while actually engaged in his comparisons; he died the day before Royal Assent was given in 1855 to the Act establishing the new measures. Thus as a result of the death of the two men who had done most of the work, the Royal Society paper in which an account of it is to be found was written by Airy. The Act (July 30, 1855) provides that:

"The straight Line or Distance between the Centres of the two Gold Plugs in the Bronze Bar deposited in the Office of the Exchequer as aforesaid shall be the genuine standard of that Measure of Length called a Yard and the said straight Line or Distance between the Centres of the said Gold Plugs or Pins in the said Bronze Bar (the Bronze being at a temperature of Sixty two Degrees by Fahrenheit's Thermometer) shall and be deemed to be the Imperial Standard Yard."

Thirty-seven copies were made and distributed.

Such were the conclusions enacted in the Weights and Measures Act of 1855, and they have remained unaltered up to the present time.

Since that date there have been various supplementary or consolidating Acts. In 1864 the Metric Weights and Measures Act was passed. It provided that "No contract . . . shall be deemed to be invalid or open to objection . . . on the ground that the Weights and Measures expressed . . . are Weights or Measures of the Metric System", and it gives a schedule of tables of metric measures expressed by means of legalised denominations of weights and measures in Great Britain, thus legalising the metric system but not providing any metric standards for purposes of comparison and verification.

In 1866 the custody of the Imperial standards of length and weight and of all secondary standards was transferred by Act of Parliament to the Board of Trade. Parliamentary copies of the yard and pound were placed at the Royal Mint, with the Royal Society, and at the Royal Observatory, Greenwich, and it became the duty of the Board to cause these to be compared every ten years with the standards in their charge. For this and other purposes connected with standards, the Board was to constitute a department to be called the Standards Office, and "shall appoint as Head of that Department an Officer to be called the Warden of the Standards", with assistants, clerks, etc., and the Act lays down the duty of the Warden.

The procedure was modified by an Act of 1878 which provided that the Board of Trade shall discharge the duties previously assigned to the Warden.

This Act also gives a schedule of metric equivalents and a list of metric standards in the custody of the Board, and provides (par. 38): "Whereas the Board of Trade have obtained accurate copies of the Metric Standards and it is expedient to make provision for the verification of Metric Weights, the Board of Trade may, if they think fit, cause to be compared with the metric standards in their custody all metric weights and measures submitted for the purpose".

A Metric Convention (Convention du Mètre) had been agreed to among a large number of nations in 1875. To this, Great Britain adhered in 1884, and comparisons between the metric and British measures were set on foot. In 1889 certified copies of the metre and kilogramme were deposited at the Board of Trade.

As a result of the comparisons carried out with great care by Mr. Chaney on behalf of the Board of Trade and M. Benôit of the Bureau des Poids et

Mesures, the value 1 metre, 39·370113 inches became the legal equivalent under an Act of 1897.

This gave to the Queen in Council power to make a table of metric equivalents in substitution for the table in the schedule to the Act of 1878 and provided that the Board of Trade standards, which may be made under par. (8) of the Act of 1878, shall include standards from the Metre No. 16 and the Kilogramme No. 18 deposited with the Board of Trade.

Under the provisions of this Act a table of metric equivalents was issued in 1898 according to which

1 metre = 39·370113 in.
1 kilogramme = 2·2046223 lb.

The most recent comparison of the yard and metre is that made at the National Physical Laboratory in 1927, which leads to the result that

1 metre = 39·370147 in.
1 inch = 25·399956 mm.

Here, perhaps, a reference to the Metric Convention is desirable. An International Metric Commission was convened at Paris in 1872 to consider the question of the construction and issue of metric standards of weight and measure. A committee was appointed to make the necessary preliminary investigations, and as the result a convention was agreed to on May 20, 1875, by a large number of States. Great Britain adhered to the Convention in 1884. The Convention provided that the contracting parties should set up at Sèvres an International Bureau of Weights and Measures at which the International prototypes of the kilogramme and metre were to be kept.

For the control of the Bureau an International Committee of weights and measures was established, consisting of fourteen members belonging to different countries. This committee was placed under the authority of a general Conference of weights and measures formed of delegates from all countries adhering to the Convention, which meets whenever convoked by the International Committee and in any case once in every six years.

INTER-DOMINION STANDARDS.

Before leaving this part of our subject—the present position of our national standards—a brief reference should be made to the Conference on Standardisation[9] held at the Board of Trade in October 1930 under the chairmanship of Mr. W. R. Smith, M.P., Parliamentary Secretary to the Board. The Conference was attended by representatives of Great Britain and Northern Ireland, the Dominions of Canada, Australia, New Zealand, the Union of South Africa, the Irish Free State, and India.

The work of the Conference was divided into two parts relating respectively to fundamental standards and to industrial standardisation. Sir Joseph Petavel acted as chairman of the section dealing with fundamental standards. The Imperial Conference held at the same time accepted the Report of the Conference on Standardisation and adopted the resolutions submitted therewith.

These resolutions, so far as they deal with fundamental standards, were:

(1) That it is desirable that there should be uniformity between the standards employed for all units of measurement which are in common use among the British Commonwealth of Nations.

(2) In order to secure uniformity arrangements should be made: (*a*) To provide in each Dominion and in India suitable reference standards for each unit of measurement required for use in that country where not already available; and (*b*) to introduce suitable procedure whereby all such standards shall be periodically compared with the corresponding standards at the Board of Trade or at the National Physical Laboratory.

(3) At least one member of the Commonwealth should undertake research work with the object of enabling the fundamental standards to be referred ultimately to natural standards such as the wave-length of light. It would be a great advantage if it were possible for research work of this character to be carried out independently by more than one member.

The Report of the Fundamental Standards Committee defines the fundamental standards both on the British system and on the metric system which constitute the fundamental units of measurement legal for use throughout the British Commonwealth of Nations. It is noted that in India the railway system of weights in common use is defined in terms of the pound.

It is explained that the term "reference standard" is used to denote a standard of suitable form and construction preserved under suitable conditions to serve as the basis of reference for the determination of any unit of measurement within one of the Dominions or of India.

In accordance with the recommendation of the Report, the errors, if any, of such reference standards in relation to the fundamental standards or to the theoretical definitions of the units they represent are to be ascertained from time to time by comparison with the corresponding standards in use in the United Kingdom, and are to be allowed for in the use of the reference standards.

The Report concludes with a list of the principal units for which reference standards are likely to be required, with suggested procedure in regard to each. Thus a simple and definite system has been set up by the Imperial Conference of 1930 for securing uniformity of standards throughout Great Britain, the Dominions, and India.

---

[9] Report of the Conference on Standardisation (including Resolutions adopted by the Imperial Conference). Presented to Parliament by command of His Majesty, Nov. 1930. Cmd. 3716. 1930.

STANDARDS OF TIME AND ELECTRICAL STANDARDS.

In addition to this account of the development of standards of length and mass, Sir Richard Glazebrook dealt briefly with time. After noting that the measurement of time rested on astronomical observations and referring to various ancient means of indicating its passage, he described in some detail the clock recently developed by Mr. Shortt in association with the Synchronome Company and the crystal vibrator constructed by Mr. Marrison, of the Bell Telephone Company, referring in connexion with these to Mr. Loomis' paper read recently before the Royal Astronomical Society. In this connexion he mentioned work now in progress at the National Physical Laboratory.

As to electrical standards, Sir Richard recalled the fact that these had been dealt with very fully up to the year 1913 in his Kelvin Lecture before the Institution of Electrical Engineers, and he restated briefly some of the principal conclusions of that lecture. Coming to more recent times, he quoted the important resolution of the International Committee of Weights and Measures of Oct. 4, 1927, approving the organisation of a Consultative Committee for Electricity to advise the International Committee of Weights and Measures on questions relating to systems of measurement of electrical standards, and, after discussing the difference between the material standards of length and mass and electrical standards for which no permanent material standards can exist, he explained the plan approved by the Committee for their work.

It is not possible to equip the Bureau with invariable material standards against which national standards can be compared. Recourse must be had to experimental determinations of the fundamental electrical units in terms of the units of length, mass, and time. The national and other laboratories of several countries are already equipped for such work, and the staffs have considerable experience. It has been agreed, therefore, to leave all such work to these laboratories, and arrangements have been made with this object; the national laboratories will from time to time send the results of their work to Sèvres. Meanwhile, the International Bureau will organise the systematic exchange of standards (étalons) and secure the co-ordination (assurer la synthèse) of the results of comparisons made by the national laboratories, and will set up a collection of working and reference standards together with the laboratory equipment for the comparison with these of the material standards sent by various countries for exact determination.

In this way, while the experimental work of realising the material standards from the electrical units of the C.G.S. system will rest with the national laboratories, the International Committee will have the responsibility of fixing and promulgating the values to be employed for practical standards, and of fixing the date of any fresh revision.

As to the values of the present international units, Dr. Dye has prepared the following table :

Values of International Units (1831) in Terms of C.G.S. Units	
International ohm .	$(1{\cdot}00051 \pm 0{\cdot}00002)\ 10^{9}$
,, ampere .	$(1 - 0{\cdot}00006 \pm 0{\cdot}00006)\ 10^{1}$
,, volt .	$(1{\cdot}00045 \pm 0{\cdot}00008)\ 10^{8}$
,, watt .	$(1{\cdot}00039 \pm 0{\cdot}00014)\ 10^{7}$
E.M.F. of Weston Normal Cell at 20° C. . .	$1{\cdot}01876 \times 10^{8}$ C.G.S. units.

NATURAL AND ARBITRARY STANDARDS.

If we look back over the history of the past, we may note some interesting changes in the views of scientific men as to the bases on which to rest their standards of measurement.

It is obvious that weights and measures began with some natural objects selected for their convenience and sufficiently constant in quantity for the simple needs of the times. Such were the length of a man's forearm or the weight of corn—possibly of water—contained in a vessel approximately constant in volume.

In time, uniformity became more important, and so we pass from the length of the king's arm to the scale engraved on the wall or floor of the cathedral, and from the weight of so many grains of wheat taken from the middle of the ear to the mass of a lump of metal.

The jury of Queen Elizabeth's time, to which we owe our modern system, paid little attention, it is probable, to the origin of the yard or the pound; they fixed on the length of a metal bar and the weight of a lump of iron and prescribed that these were to be the standards, trusting to the permanence of these material objects rather than to any natural laws which might serve for their definition. They were, no doubt, severely practical; a change came in England in the early days of the Royal Society, when we find Caswell and Walker endeavouring to connect the weight and volume of a quantity of water and thus establish a natural standard of weight in terms of the standard of length—trying possibly to repeat what had been done in Egypt long ago.

Then, some fifty years later, Graham, realising that there was a definite relation between the period of a body in oscillation, its dimensions, and the distribution of its mass, endeavoured to connect the period of a seconds pendulum with its length, and set about the comparison of existing material standards, to find one in terms of which to express the length of the pendulum, thus leading to the Report of Lord Macclesfield's Committee in 1743.

Inter-comparisons between existing standards continued to be made, and the idea of basing that of length on the seconds pendulum increased in favour, until in 1814 the House of Commons asked for a formal statement of the length, and two years later the Astronomer Royal was instructed to determine it. Kater's work followed, with the result that, while in 1824 certain material standards—Bird's bar of 1760 and a brass weight of 1 lb. troy dated 1758—were made the legal standards, they were to be recovered, if lost, by reference to natural standards, the length of the seconds pendulum and the weight of a cubic inch of water.

This recourse to natural standards did not last long. Scientific men discovered that it was simpler to compare a standard with its copies, and to recover its value, if lost, by the aid of those copies, than to determine the length of the seconds pendulum or the mass of a cubic inch of water, and so, in 1843, the recommendations of 1824 were thrown over; the scientific committee, appointed to advise, recommended that the standards which had been lost in the fire of 1834 should be recovered from their copies, "and that the Standard be in no way defined by reference to any natural basis". More trust could be placed in the permanence of a material standard and on the accuracy with which it could be recovered by the inter-comparison of its copies, than on the result of any attempt to reconstruct it, based on some natural law; and so it has remained up to the present.

In France the history has been the same. The Constituent Assembly entrusted the Academy of Sciences with the duty of introducing a new system of measures, and in 1788 a report was issued on the choice of a unit of measure drawn up by Borda, Lagrange, Laplace, Monge, and Condorcet.

The report discussed the advantages of employing either the length of the seconds pendulum or that of a meridian of the earth as the basis of length measurement, and decided in favour of the latter, which, in the words of Laplace, "appears to be of very high antiquity". So the metric system came into being. Delambre and Mechain measured the length of an arc from Dunkirk to Barcelona, and hence calculated the length of the quadrant as 5,130,740 of a certain iron Toise, when at a temperature of 61·5° F. The metre was fixed as one ten-millionth of this length, and a standard metre constructed to represent it, while the kilogramme was to be the mass of a cubic decimetre of water at the temperature of its maximum density, and a platinum weight was constructed with great care to have this mass when weighed *in vacuo*.

While these material standards continue to exist, research has shown that they no longer represent the definitions. The metre is still the distance between the marks on a certain bar of platinum iridium, but the earth's quadrant is not 10^7 of these metres, while different meridians differ in length; the earth is not a spheroid. The best mean figure obtainable seems to be 1 meridianal earth quadrant $= 10{,}002{,}090$ m.

The platinum mass, known as the Kilogramme des Archives, is still the standard kilogramme, but the mass of a cubic decimetre of water, at 4° C. approximately, has been found to be 999·972 grammes, or alternately 1000·028 c.c. is the volume of a kilogramme of water at the temperature of its maximum density and under normal atmospheric pressure.

Neither the seconds pendulum nor a quadrant of the earth has proved to be more satisfactory than the material standard. This was the case when Michelson in 1889, realising that the wave-length of light of a given frequency was invariable, suggested its use as an ultimate standard of length. There was the difficulty of stepping from so small a unit as a wave-length of light up to the metre, but he pointed out that one can bridge over the distance by using a number of standards each approximately, but not quite, double the distance of the last, employing interference methods to determine the difference between the length of the larger standard and twice that of the smaller. Light directed so as to traverse the smaller distance twice was made to interfere with light which has only once traversed the longer distance. Michelson had an opportunity of carrying this idea into practice somewhat later at the Bureau des Poids et Mesures at Sèvres, and found from observations on the red line of cadmium that its wave-length is given by

$$\lambda_R = 0{\cdot}64384722 \times 10^{-6} \text{ metre.}$$

Somewhat later, in 1913, Messrs. Benoit, Fabry and Perot at the Bureau International repeated the measurement, using a modification of the method, and found

$$\lambda_R = 0{\cdot}64384704 \times 10^{-6} \text{ metre.}$$

Since that date measurements have been made in Japan by Messrs. Watambe and Timaszumi, leading to the value

$$\lambda_R = 0{\cdot}64384685 \times 10^{-6} \text{ metre,}$$

while Dr. Tutton communicated to the Royal Society on April 30 last his results, which gave

$$\lambda_R = 0{\cdot}64384698 \times 10^{-6} \text{ metre.}$$

A provisional value found at the National Physical Laboratory is

$$\lambda_R = 0{\cdot}64384714 \times 10^{-6} \text{ metre.}$$

At its meeting in 1925 the International Committee of Weights and Measures agreed in principle to define the unit of length by means of the wave-length of light, subject to the determination by the national laboratories of the most satisfactory method of realisation.

As a result, work has been in progress at the National Physical Laboratory for some time, and now is approaching conclusion, while work is also in progress at the Reichsanstalt and the U.S. Bureau of Standards.

Thus it will be seen that the International Committee is prepared to refer the standard metre to a natural standard against which it can be compared. This natural standard will thus be represented by the distance between two marks on a bar of platinum-iridium, and the constancy of this distance will be checked from time to time by comparison with the wave-length of light of definite period.

Hence there is a prospect that a natural standard of length will in time be generally accepted.

As to a standard of mass, up to the present it is not probable that the kilogramme, the mass of a lump of platinum, will be disturbed until we reach the condition when the mass of an atom of hydrogen or (say) an electron can be determined with sufficient accuracy. For a time unit, we already have a natural standard in the sidereal day, and while the frequency of a quartz or other oscillator will certainly be used for comparatively short intervals, it will not replace the day and hour for longer periods.

In electrical standards also a transference to natural standards is taking place. One of the first duties of the Comité Consultatif d'Électricité set up in 1927, as has been stated, is to determine the units in terms of which electromotive force, current, and resistance are to be measured. At present, while the units are defined in terms of the C.G.S. units of length, mass, and time, the standards used in daily work are the International Ohm, Ampere, and Volt. The definitions of these, as has already been explained, were agreed to at the International Conference in London in 1908.

The appliances needed for an absolute determination of the electrical units are elaborate and expensive. At the time of the London Conference it was realised that the necessary measurements could be made only in a few well-equipped standardising laboratories, while it was felt that the standards for daily use should be such as could be set up without serious difficulty in any laboratory provided with ordinary measuring and weighing apparatus of adequate precision. Hence the adoption of International Standards.

The arrangements proposed at Sèvres by the Comité Consultatif d'Électricité have altered this. When these are complete, any country can have its electrical standards compared against standards maintained at the Bureau, while by the collaboration of countries possessing laboratories, equipped for absolute measurements, these standards can be realised and maintained in much closer agreement with the C.G.S. units than is now the case with the International Ohm, Volt, and Ampere.

Since 1928, and indeed previously to that date, work has been in progress at the National Physical Laboratory in connexion with all the units.

The Ampere balance has been reconstituted; work has been put in hand on a novel method of measuring a resistance suggested some years since by Albert Campbell; preparations are going forward for further measurements with the Viriamu Jones Memorial Lorenz apparatus, and for a re-determination of the electromotive force of a Weston cell.

At the second meeting of the Comité Consultatif d'Électricité in 1930, reports as to progress were received from the National Physical Laboratory, the U.S. Bureau of Standards, the Central Chamber of Weights and Measures of Russia, and the Electrotechnical Laboratory of Tokyo.

While, of course, it will be necessary to have at Sèvres material standards or apparatus embodying the results of these various absolute measurements, the standards and apparatus will represent, with all the accuracy possible, multiples of the C.G.S. units themselves, and not standards adopted because, at the time they were defined, they were believed to represent the theoretical units to the highest accuracy then possible.

Thus in electricity we go back through the C.G.S. units to the natural standards of length and time, the wave-length of the red line of cadmium and the sidereal second.

evidence of a large increase in public interest in the Exhibition Galleries in the Institute, the attendance during the year being 608,900, as compared with 398,000 in 1929. The more important work of the Institute, however, in advising as to the utilisation of the resources of raw materials in the British Empire and in promoting the production within the Empire of crops and products which at present are mainly obtained elsewhere, is still hampered by lack of funds. The Research Committee of the Imperial Conference, which met in London in 1930, investigated the Intelligence and Investigation Departments, which are mainly concerned with this vital but less publicly known work of the Institute, and recorded its opinion that this work could be carried out more efficiently and less expensively through the utilisation of the services of the Imperial Institute than in any other manner. During the present Empire-wide depression, no further Government funds are available to extend the Institute's work, but in March 1931 the Secretary of State for the Dominions was able to announce that Mr. Benjamin Drage had contributed £36,000 to the Empire Marketing Fund with the proviso that the sum, to be spread over a period of seven years, should be used to augment the income of the Imperial Institute. The Institute not only advises the Colonies and Dominions upon mineral resources; it is also busy trying to develop the production of commodities like tung oil, pyrethrum flowers, and so on within the British Empire, and is able to report that the London County Council has approved five Empire woods as fire-resisting timbers. The perusal of the Director's brief report will show how wide-flung are its activities.

Mr. J. Milton Offord has contributed to the March *Journal* of the Quekett Microscopical Club some interesting recollections of his association with the Club since 1878. At the meeting in January 1879, at which he was elected a member of the Club, Huxley was in the chair and E. T. Newton showed a model of the brain of the cockroach, constructed from slices of wood of appropriate thickness representing the successive serial microscopic sections of the brain. The outlines of the section had been drawn on the slices with the help of a camera lucida and cut out by a fret-saw. These prepared slices when fitted together formed the model—one of the early examples of a method which, after modifications, was, especially in the next twenty years, and still is, regularly employed in many laboratories. Mr. Offord refers to the large conversaziones which were a feature of the society's activities, and directs attention to one held in University College, London, in 1879, at which there were 185 microscopes, and 1050 persons were present. This was regarded as a small attendance for a conversazione and "was put down to the inclement weather, and it being held during Lent".

On June 27, Prof. G. M. Trevelyan, O.M., representing the National Trust, accepted the deeds of the property of the Longshaw estate for the Trust. This estate is 750 acres in extent, and is the first acquisition made by the National Trust in the Peak district of Derbyshire. It is a beautiful stretch of high woodland and moorland, surrounded by picturesque heights. When it was offered for sale, a sum of £15,000 was asked for the complete estate, and, since it was threatened to be disposed of as building sites, the Sheffield Council of Social Service and the Sheffield and Peak District branch of the Council for the Preservation of Rural England took steps to save the estate. £11,000 came from the city and neighbourhood of Sheffield and £3580 from other parts of the country, chiefly through the National Trust. The deeds of the estate were handed over to Prof. Trevelyan by Mrs. Gallimore, honorary secretary of the Longshaw committee.

On June 24 the Royal Society of Tropical Medicine and Hygiene moved its offices from Chandos Street to Manson House, 26 Portland Place, which has been secured as its permanent home and as a memorial to the late Sir Patrick Manson. With the help of Joseph Chamberlain, then Colonial Secretary, Manson founded the London School of Tropical Medicine in 1897; other countries followed suit and similar institutes have been set up in Hamburg, Amsterdam, Paris, and other centres. It was soon realised that this new knowledge should be co-ordinated, and in 1907 Sir James Cantlie, Dr. Carmichael Low, and others founded the Society of Tropical Medicine and Hygiene, with Sir Patrick Manson as its first president. Though Manson died in 1922, there was no adequate memorial to him, and last year the council of the Society resolved to buy and equip a house which should be known as Manson House in memory of Sir Patrick, and at the same time form a permanent home for the Society. A sum of about £11,000 has been collected and subscribed for this purpose, but a further £17,000 is required to complete the scheme. Any donations, great or small, will be gratefully acknowledged if sent to the president, Manson House, 26 Portland Place, London, W.1.

Sir Sidney F. Harmer, formerly Director of the Natural History Departments of the British Museum, has been elected an honorary member of the Société Zoologique de France.

The South Africa Medal for 1931 of the South African Association for the Advancement of Science has been awarded to Prof. H. B. Fantham, of the Department of Zoology and Comparative Anatomy in the University of the Witwatersrand, Johannesburg, for his researches on parasitic protozoa, soil protozoa, and heredity. The medal is being presented to Prof. Fantham at the Grahamstown meeting of the Association on July 6.

The Museums Association will hold its annual conference this year at Plymouth on July 6–11. All meetings of the Association will be held in the Abbey Hall. July 6 will be spent in committee meetings, and the president, Sir Henry Miers, will deliver his presidential address on July 7. The president's address will probably include some indication of a proposed survey of all the museums in the British Empire, to be financed by the Carnegie Corporation of New York. Among the papers to be read are: "A Suggested System of Museum Registration", by Mr. K. de B. Codrington, and "Paper for Museum Labels", by Dr. L. J. Spencer, on July 8; "Taxonomy in the

Museum", by Dr. W. T. Calman, "Present-Day Problems of Provincial Museums", by Mr. H. J. M. Maltby, and "The Preservation of Marine Life, Wet or Dry Specimens", by Dr. E. J. Allen, on July 9; and "Museum Problems in Canada", by Prof. J. H. Iliffe, "A Simple Way to test Museum Value", by Dr. Hay Murray, and "Why do we use Plate-Glass in Museums?" by Mr. Frank Loney, on July 10. All communications concerning the Conference should be addressed to the local honorary secretary, Mr. A. J. Caddie, Museum and Art Gallery and Cottonian Collection, Plymouth.

THE Report of Map Publication and Office Work of the Survey of India for 1929–1930 (Calcutta, 1*s.* 9*d.*) is chiefly useful for the detailed index sheets of published maps of India and adjacent countries. Good progress is being made with all the maps. The 'million' map is now practically complete for India, Burma, and adjacent countries. The modern '1-inch' map is making progress, and the modern '¼-inch' covers considerable areas in the most important parts of India. Additions have also been made to several other series.

THE last issue of the League of Nations *Quarterly Bulletin of Information on the Work of International Organisations*, No. 2, vol. 3, April 1931, contains brief reports of some three dozen conferences held and also a list of more than sixty forthcoming conferences to be held during the present year. It is desired to make this register as complete as possible. Information about coming scientific conferences of international importance would be particularly welcome and may be addressed to the Section of International Bureaux, League of Nations, Geneva.

MESSRS. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, have just circulated an important catalogue (New Series, 25) of second-hand works (more than 2000 in number) on entomology and arachnology, including the collection of pamphlets formed by the late W. F. Kirby. The list is obtainable upon application.

A USEFUL catalogue (No. 458) of about 900 second-hand books on philosophy, including many from the library of the late W. E. Johnson, Sidgwick lecturer in moral science in the University of Cambridge, has just been received from Messrs. Bowes and Bowes of Cambridge. Copies can be had from the publishers upon application.

MESSRS. H. K. Lewis and Co., Ltd., have just issued a supplement (1928–1930) to the catalogue of their Medical and Scientific Circulating Library which should be of service not only to users of the library, but also to others who may wish for particulars of books relating to science in its various branches. The supplement is arranged alphabetically, but a classified list of subjects included, with the names of the respective authors, is given at the end. The price to subscribers is 1*s.* net., to others 2*s.* net.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant quantity surveyor on the staff of the Miners' Welfare Committee of the Mines Department—The Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S.W.1 (July 8). A secretary of the Institution of Sanitary Engineers—The Chairman of Council of the Institution of Sanitary Engineers, 120-122 Victoria Street, S.W.1 (July 8). A visiting teacher of science capable of teaching physics and chemistry, hygiene, and some biology in the junior day school of the Smithfield Institute—The Education Officer (T.1), County Hall, S.E.1 (July 10). An assistant in the natural history division, National Museum, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C.8 (July 10). A lecturer in mining at the Sunderland Technical College—The Chief Education Officer, Education Office, 15 John Street, Sunderland (July 11). A full-time lecturer in charge of the electrical engineering department of the Chesterfield Technical College—The Principal, Technical College, Chesterfield (July 11). An assistant master at the Bolton Municipal Technical College, to teach mainly science subjects in the junior technical school and engineering departments of the College—The Director of Education, Education Offices, Nelson Square, Bolton (July 11). A librarian of University College, Nottingham—The Registrar, University College, Nottingham (July 13). A principal of the Neath Mining and Technical Institute—The Director of Education, County Hall, Cardiff (July 13). An assistant lecturer in physics at University College, Nottingham—The Registrar, University College, Nottingham (July 13). An assistant organising lecturer at University College, Nottingham, under the Miners' Welfare Adult Education Joint Committee—H. L. Featherstone, 14 Shakespeare Street, Nottingham (July 14). A woman senior demonstrator in pathology at the London (Royal Free Hospital) School of Medicine for Women and Royal Free Hospital—The Warden and Secretary, 8 Hunter Street, W.C.1, or the Secretary, Royal Free Hospital, W.C.1 (July 15). A lecturer in zoology at Birkbeck College—The Secretary, Birkbeck College, Fetter Lane, E.C.4 (July 15). A principal of the Harris Institute, Preston—Alderman H. Astley Bell, Harris Institute, Corporation Street, Preston (July 31). A keeper of archæology in the Liverpool Public Museums—The Town Clerk, Municipal Buildings, Dale Street, Liverpool (Aug. 1). An assistant town planner under the Government of Northern Rhodesia—The Crown Agents for the Colonies, 4 Millbank, S.W.1, quoting M/2748. A lecturer-in-charge of the building department of the Norwich Technical College—The Principal, Technical College, Norwich. Teachers of engineering drawing and mechanical engineering at the East Ham Technical College—The Secretary, Education Office, Town Hall, East Ham, E.6. A teacher of engineering at the Leyton Technical College—The Clerk to the Governors, 280 High Road, Leyton, E.10. A Principal of University College, Leicester—The Registrar, University College, Leicester.

Embryology and the Theory of Polyhedra.

A new volume of *Proceedings* of the Bologna Mathematical Congress begins with a short paper by Max Brückner, on the old problem of how many different polyhedra are possible of n sides—with the limiting condition that all the corners shall be trihedral. In my book on "Growth and Form" I dealt with the kindred problem of the possible number of arrangements of a plane assemblage of cells, their partition-walls all meeting three-by-three, as is actually the case in a system of soap-bubbles or of living cells. The problem of the polyhedra is just as interesting to the biologist; for any 'natural clump of cells, such as a totally segmented egg or 'morula', may be looked on as a polyhedron and may be studied accordingly.

Eighty years ago, Kirkman showed that the total number of 8-sided (convex, Eulerian) polyhedra, with trihedral corners, was *thirteen*; and Cayley, Steinitz, and others have extended the problem by a few stages. The number of possible arrangements increases rapidly; and now Brückner (whose results I only quote approximately) tells us that, for

$n = 13$, 14, 15, 16, the number of
n-sided polyhedra $= 5 \times 10^4$, 4×10^5, 3×10^6, $2{\cdot}7 \times 10^7$.

An 8-sided polyhedron, or 8-celled egg, may have its sides, or cells, arranged in 13 different ways; there is room for variety, but withal so limited that we must expect to find the same arrangement, or cell-pattern, repeated again and again in the 8-celled stages of divers organisms. But we no sooner come to the 16-celled stage than nearly 30 million arrangements of these sixteen cells are found to be possible. And it becomes plain that the study of 'cell-lineage', or the mapping-out in detail of the cell-arrangements after repeated cell-divisions, is only possible under the severest limitations—if it be possible at all.

St. Andrews.

Effect of Certain Substances and of Heat on Cells of *Abraxas*.

In continuation of the work already carried out last year on the effects of phosphorised olive oil on the male germ cells of *Abraxas*, we have investigated material from larvæ injected into distilled water, 2 per cent NaCl in water, phosphoric acid, and phosphorus in paraffin oil. We have also tried various temperatures for several hours.

In many of the preparations, in addition to the cytoplasmic inclusions, the spindle bridges, or parts thereof, swell up and form separate bodies, which are very similar to the abortive acroblasts already described. In material treated with phosphoric acid, heat, 2 per cent NaCl in water, and phosphorised paraffin oil, no very large bodies of the type already described[1] have yet been found. There is at present some doubt as to the actual mode of origin of some of these large elements in the spermatocytes and spermatids of *Abraxas*.

Paramagnetism of Bivalent Silver.

In collaboration with Mr. F. H. Burstall, one of us has recently prepared a series of silver salts of the type $[\mathrm{Ag\ 3\ dipy}]X_2$ in which dipy represents αα′-dipyridyl ($C_{10}H_8N_2$) and X a univalent anion (*J.C.S.*, 2594; 1930). The complex kation is therefore bivalent.

If this is due to the presence of bivalent silver, then an electron must have been extracted from the inner levels (probably the N level) of the silver atom, which consequently should be paramagnetic. We have therefore measured by the Gouy method the susceptibility of the chlorate at 20°. Parallel measurements were made in the same apparatus with copper sulphate, since the bivalent copper ion contains a similar incomplete sub-group. The following results were obtained:

Substance.	χ.	χ_M.	p.
$CuSO_4{\cdot}5H_2O$	$5{\cdot}86 \times 10^{-6}$	1457×10^{-6}	9·2
$[\mathrm{Ag\ 3dipy}](ClO_3)_2$	$1{\cdot}93 \times 10^{-6}$	1434×10^{-6}	9·1

The molecular mass susceptibilities of the silver and copper compounds are equal within the limits of the experimental error (5 per cent). The Weiss magneton number p is calculated on the assumption that the Curie law holds, and no allowance has been made for the diamagnetism of the rest of the molecule. The values are, however, in fair agreement with those found for other atoms in which a sub-group lacks one electron: for example, $Cu^{\cdot\cdot}$, 9·2; NO, 9·2; $VOSO_4$, $3\frac{1}{2}H_2O$, 8·95, $V_2O_2Cl_4{\cdot}5H_2O$ 7·94. These values are taken from the International Critical Tables.

Forestry Practice and Research.

The leader on forestry research in Nature of May 16, and previous letters from Dr. Rayner and Prof. Tansley, would suggest that attempts to grow timber on poor land are in their infancy, and that the work of the Forestry Commission and other State forest departments throughout Europe is being carried on in complete ignorance of fundamental principles. It is fairly evident that no representation of this kind was intended, but at the same time the impression might be conveyed to the casual reader (if such an individual ever reads Nature) that research in connexion with afforestation has been practically ignored. This view may be perfectly correct in certain directions, but I think the practical forester is as fully aware of the value of genuine research as those engaged in any other industry influenced by biological factors. As regards the British forester, whether in the capacity of employer or employee, I scarcely think that he is guilty of the charge advanced by Prof. Tansley. Forest botany and pedology he may have failed to study through lack of opportunity, but in connexion with geographical botany, estate owners throughout the British Isles have carried out most valuable work for practically two centuries in testing exotic species on varying soils and situations. These tests of exotic species have already enabled two or three cubic feet of timber to be grown where only one grew before in connexion with the planting of species like Douglas fir or Sitka spruce, while they have conclusively proved the unsuitability of other species for the British climate, although strongly advocated by enthusiasts.

We know that many of the empirical methods adopted in farming and gardening have been explained, and in many cases justified, by science; others have been shown as useless or harmful; while in connexion with insects and fungi, invaluable weapons have been placed in the hands of the modern cultivator by science and research. But no one suggests that gardening or farming are industries which should have stood still until science had investigated them in all their aspects. Some years ago the Development Commission, which at that time was in charge of forestry development, adopted the principle that education and research should precede practical operations. Had this policy been adhered to, twenty years might have elapsed before a single plantation had been laid down with the aid of public money, while private planters in every direction had already provided, throughout the length and breadth of the British Isles, abundant examples of practical timber growing, good, bad, and indifferent.

---

[1] Gatenby, J. Brontë, *Jour. Exper. Zool.*, vol. 58; 1931.

The Forestry Commission only came into existence in 1919, and had a definite function to perform, namely, the building up of a timber reserve within a definite period. Had it been able to confine its operations to soils and sites comparable to those which had already carried successful timber crops, the problem, from a technical point of view, would have been comparatively simple. It is no secret, however, that many areas have been acquired which are not likely to fulfil all that was expected of them, and it is on these that the scientific worker might carry out invaluable work if given the opportunity and encouragement.

So far as the practical man is concerned, however, the soil is the raw material upon which he has to work, and it is no exaggeration to say that he knows practically nothing about it other than a few of its more obvious mechanical and physical features. But this does not prevent him from growing cabbages or potatoes satisfactorily. On similar lines the forester plants trees and produces timber which he considers will meet a local or general demand some day or other, but it does not follow from this that he is able to explain how these trees grow, nor can he anticipate the results of his work within exact limits. The man of science may be able to influence him as regards his methods to an appreciable extent, but every cultivator, whether of farm, garden, or forest crops, knows perfectly well that he does many things badly for the simple reason that he cannot do them in any other way under average conditions. Weather and other natural causes over which he has no control frequently dominate the most carefully conducted operation, and unless the latter can be carried out as cheaply as the more rough and ready process to which experience has accustomed him, he is naturally apt to view innovations with suspicion.

In connexion with the branch of research already alluded to, namely, the introduction of exotics from the more temperate parts of the world, several instances might be given to show that experience, when properly interpreted, is the only safe guide in the long run. For example, the success of Weymouth pine in the British Isles (apart from *Peridermium Strobi*) would lead one to suppose that other species growing within the same region would also succeed. Yet *Pinus resinosa*, a useful timber tree in Canada, fails in this country, although associated with Weymouth pine in its native habitat. In Eastern Canada, *Pinus Contorta* is, as its name implies, a scrub pine, while in North-western Europe it grows, in the earlier stages at least, faster than any coniferous species on the poorest type of soil. Many similar examples of this kind could be given, yet probably the scientific worker, basing his conclusions on meteorological data, would give erroneous advice on matters of this kind.

The moral of all this appears to be that practice and science must work side by side, and regard themselves within their own spheres as equally important, neither trying to influence the other until the problem at issue is thoroughly understood.

The practical man has no grievance against research workers. On the contrary, he has every reason to welcome them. But it frequently happens that research confines its attention to one particular problem, and is inclined to dogmatise upon it, whereas the industry to which it applies is made up of a complex system of science, practice, economics, and politics which the research worker has no particular reason to consider. Every practical forester recognises the fact that soil and the root functions of the tree growing in it are mysteries which he cannot unravel unaided, and the article in NATURE on May 16 will be welcomed by every unprejudiced worker in the forestry field.

A. C. FORBES.

Dublin, June 15.

The Age of Flint.

A HUNDRED years have elapsed since Mantell opened the controversy regarding the formation of flint, but hitherto, despite a voluminous literature on the subject, the crucial point, the time of formation, has remained undecided. The main issue has been narrowed down to one of two possibilities: either the flint was formed contemporaneously, by precipitation of silica gels on the sea-floor, or it was formed subsequently to the deposition of the Chalk, by the solution and segregation of silica disseminated through the chalk chiefly from the remains of sponges. The arguments in favour of the rival views are fairly evenly divided, and a strong case can be made out for both contemporaneous and subsequent formation. In fact, almost every observation can be made to fit in equally well with either view; and, like the evidence, so the supporters of the theories, past and present, are evenly divided. An infallible criterion of the age of flint is, therefore, a prime necessity, and the purpose of this note is to suggest one, of which the only remarkable feature is its extreme simplicity. The condition of the sponge remains found in flint is in itself adequate proof that the formation was subsequent.

Siliceous sponges may be divided, according to their behaviour after death, into two classes, namely: (*a*) those in which the skeleton is composed of separate spicules and which rapidly disintegrate after death, the spicules becoming scattered; and (*b*), those in which the skeleton consists of a continuous framework, with separate spicules scattered in its meshes. To the latter belong the Lithistida and the Dictyonine Hexactinellida. Judging by experience of hauls of recent sponges from waters of all depths, it is probable that the time taken for the disintegration of those of class *a* may be from a few months, or less, to a year, seldom more. As to those of class *b*, although the interstitial spicules may be lost in a few months, or less, the dictyonine framework may persist for years. In fact, it is indestructible except by severe mechanical abrasion or continued action of solvents over a long period of time. Normally, therefore, the Dictyonine Hexactinellida and the Lithistida will stand the greatest chance of preservation where sedimentation is slow, and in any deposit laid down in depths of 100 to 1000 fathoms, where the two classes are approximately equally represented, the higher the rate of deposition the more of class *a* will be preserved as complete sponges, and the more likelihood of interstitial spicules being found in the skeleton of class *b*.

The sponge-remains in the English chalk belong predominately to class *b*; in fact, the number recorded for class *a* is negligible. Moreover, the interstitial spicules of the former are, practically without exception, lost. In other words, the sponge remains are precisely those which would be left after a long period of disintegration on the sea-bottom. These remarks apply equally well to remains found in chalk and in flint. Clearly, then, these remains suffered no rapid burial. Had the sponges found in flint been entombed by a fall of silica gel, a few complete and live sponges at least would have been embalmed in the process. It may, indeed, be said that the majority would be intact, and we should have had a large number of class *a* so preserved. Yet despite the numbers of flint nodules which must have been examined in the last century, we have nothing to show of class *a* except for isolated spicules. Nothing could be more decisive.

Frequently, one finds in flint the dictyonine framework of a sponge faintly portrayed in a brown stain, and the connexion between these and similar iron-stained impressions in the surrounding chalk is obvious. The replacement of the original silica by iron oxide must have taken place prior to the formation of the flint, showing clearly that that formation was not only subsequent, but also took place a long time after the burial of the sponge-remains.

There is yet one other factor, which also seems to have been completely overlooked. If flint had been formed by the relatively sudden precipitation of silica from solution, we have to explain why the remains of all forms of contemporary life found in it are so poor. Taking the Rhynie chert of Aberdeenshire as an example, in which remains of plants and animals, many of minute size, are so beautifully preserved, we should expect to find much better preservation of the fossils enclosed in flint. The famous Whittaker's three-inch, representing a continuous bed estimated at some 240 square miles in extent, should have embalmed a perfect representation of contemporary benthos. Yet this, and other flint similarly bedded, fails entirely in this respect.

The story of the formation is even yet far from complete, but that that formation was subsequent to the deposition of the chalk, nobody who has worked extensively at both recent and fossil sponges will deny.

Absorption Spectra of Crystals at Low Temperatures as References in the Measurement of Stellar Velocities.

THE vast work of determining and cataloguing radial velocities has made the slitless spectrograph almost indispensable. A number of stars may then be photographed on the same plate at the same time. Such a method is possible only if the starlight passes through some medium which has sharp absorption lines so that the spectrum of each star has within it the absorption lines for references. A medium having sufficiently sharp lines in the proper spectral region does not seem to have been found. I would suggest the use of the crystals of the rare earths maintained at the temperature of liquid nitrogen. Both Dr. Joy, of the Mount Wilson Observatory, and Dr. Shane, of the University of California, have considered in this connexion the absorption spectra of crystals of gadolinium at room temperature.[1] The absorption lines occur, however, in an unfavourable region of the spectrum.

The spectrum of the dysprosium ion appears particularly adapted for the purpose. At room temperature its spectrum taken with a three prism Steinheil spectrograph contains some diffuse lines between 4000 A. and 4800 A. At the temperature of liquid nitrogen, the lines are as sharp as those of gases. The crystal studied was dysprosium ethyl sulphate. It is possible, though not easy, to grow this crystal perfectly clear. A few trials would doubtless discover a more amenable salt of dysprosium. The acetate is probably easy to grow. A crystal about 2 cm. × 2 cm. × 0·5 mm. of another rare earth, cerium, was grown almost as clear as glass by evaporating a saturated solution in a desiccator containing concentrated sulphuric acid. Much larger crystals can be obtained when some precautions are taken as in the method of Freed and Spedding.

Because of its constant boiling point, liquid nitrogen is preferable to liquid air, by means of which it may readily be prepared. Also, it has the advantage of complete transparency should one desire to immerse the crystals in the refrigerating liquid.

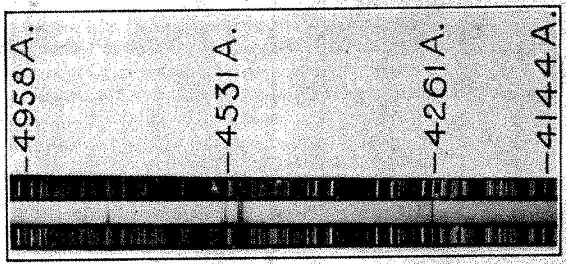

FIG. 1.—Absorption spectrum of dysprosium ethyl sulphate ($Dy_2(SO_4)_3 . 9H_2O$) at the temperature of liquid nitrogen.

The high cost of dysprosium might induce one to investigate other rare earths. Neodymium has also been found to possess sharp absorption lines in this spectral region, but they are not so fine as those of dysprosium. However, it is not necessary to employ pure salts of dysprosium. It may be desirable, also for spectrographic reasons, to make a mixed crystal with the corresponding colourless lanthanum salt.

No difficulty should be met in eliminating any serious change in temperature of the spectrograph because of the liquid nitrogen.

I wish to express my indebtedness to Mr. G. P. Kuiper, of the Leyden Observatory, for an interesting conversation. The work is one of a number made possible through the generous hospitality of Prof. W. J. de Haas. The Steinheil spectrograph was kindly placed at my disposal by Prof. W. H. Keesom.

Mortality among Plants and its Bearing on Natural Selection.

I HAVE read with great interest the letters from Prof. Salisbury and Dr. J. Phillips which have appeared in NATURE dealing with mortality in plants at different stages of their life histories. The observations are of the greatest importance, but I doubt whether the interpretation advanced by Prof. Salisbury in his letter of May 31, 1930, is supported by the facts. It seems to me that a distinction should be made between mortality and natural selection. The results obtained by Prof. Salisbury with *Silene conica L.* and *Verbascum Thapsus L.* would probably have been very similar if all the seeds in each case had been exactly alike, and, in any case, evolution under natural conditions is proceeding so slowly that individuals of any one species or variety in a taxonomic sense are very nearly identical. On the other hand, the seed yield of many individual plants runs into thousands and millions, which, combined with the losses between pollen production and germination, makes the chances against survival into the second generation of any single pair of gametes enormous. How far natural selection enters into this enormous mortality can never be known: for while accidental mortality deals equally with the less and the more favourable variation, competition verging on mortality puts a high premium on favourable variations, however small, as, for example, in competition for light or plant food.

With regard to the taxonomic characteristics of adult plants, it can for the moment be fairly assumed that they have been attained as a result of intense natural selection extending over millions of years, in which case little difference between individuals is to be expected, and little scope for progressive selection will exist. Whatever differences exist in the relative fitness of adult stages will be reflected in the seed yield, and I have frequently been struck by the wide variations in seed yield between different individuals of *Capsella Bursa-pastoris*, *Brassica Sinapis*, *Senecia vulgaris*, and *Bromus mollis*. One individual of these species may easily give rise to a hundred times more seed than another, so that even allowing for accidental differences of soil and situation the scope for natural selection in adult stages is fully comparable with that for seedlings.

The whole subject of seed yield, reproduction rate, and frequency of occurrence in plants needs careful study; since in all species a very delicate balance exists between rate of reproduction and mortality, and the slightest change in these should lead to striking changes in frequency in species with short life histories; yet observation shows that this is not the case. Assuming for the moment a habitat occupied by only one species, the number of adult individuals present would probably be very stable for wide differences in seed yield. If, however, *Lolium perenne*, *Dactylis glomerata*, *Bellis perennis*, *Taxacum Dens-leonis*, *Ranunculus bulbosus*, and *Carduus lanceolatus* are all present in one pasture, why does not one species drive out all the rest, and why is *Lolium perenne* usually more abundant than *Dactylis glomerata*, and *Ranunculus bulbosus* more common than *Taraxacum Dens-leonis*? In raising these questions, and in remembering rare individuals of still rarer species, one is driven to conclude that suitability to a given habitat plays a predominant rôle in the frequency of occurrence of a given species. One single favourable variation, when fully established, ought to have a marked influence on the frequency of a given species comparable with the results obtained by changing the habitat artificially, as, for example, by liming and draining. From the evidence before us, I must tentatively conclude either that nearly all mortality in plants is not progressively selective, or that progressive variations are occurring at such a rate that they are almost completely eliminated before they became established.

The Heat of Dissociation of Fluorine.

The heat of dissociation of chlorine, bromine, and iodine has been determined by thermal methods by Bodenstein and estimated respectively to be + 56·8, + 45·2, + 35·6 kilo-cal. No data are yet known regarding the heat of dissociation of fluorine.

I have determined this quantity by reversing the arguments of Franck regarding the absorption spectra of molecules of alkali halogenides. It is well known that the alkali halogenide vapours like NaCl, etc., give a continuous absorption spectrum, the beginning of absorption corresponding to the atomic heat of formation $R = \mathrm{Na} + \mathrm{Cl} - \mathrm{NaCl}$. R is connected with the ordinary heat of reaction $Q . \{Q = [\mathrm{Na}] + \frac{1}{2}\mathrm{Cl}_2 - [\mathrm{NaCl}]\}$ by the relation $R = Q + \frac{1}{2}D_{\mathrm{Cl}_2} + \lambda_{\mathrm{Na}} - \lambda_{\mathrm{NaCl}}$, where D_{Cl_2} is the heat of dissociation of Cl_2; λ_{Na} is the heat of vaporisation of Na, λ_{NaCl} is the heat of vaporisation of [NaCl] crystals. It is found that if ν_0 be the frequency of the beginning of absorption, then $h\nu_0$ corresponds almost exactly to the value of R calculated as above in the case of ionic compounds.

I took anhydrous NaF and KF and vaporised them within a silica tube placed within the vacuum graphite furnace of this laboratory, and obtained their absorption spectra. For NaF, the absorption became noticeable at λ2370; for KF at λ2245. We can then calculate D_{F_2} from the relation $\frac{1}{2}D_{\mathrm{F}_2} = R - [Q + \lambda_M - \lambda_{MF}]$ in which R is calculated from the absorption spectrum data, the other quantities are taken from Landolt and Bornstein's tables. From NaF data, we get $D_{\mathrm{F}_2} = 78$ kcl., from KF data we get 74 kcl. It appears, therefore, that the heat of dissociation of fluorine is: 76 ± 2 kcl.

I propose to complete the work by performing similar experiments with other alkali fluorides.

Hyperfine Structure in the Rubidium Spectrum.

In a preliminary note[1] the lines of the rubidium doublet $1S_{\frac{1}{2}} - 3^2P_{\frac{3}{2}}$ and $1S_{\frac{1}{2}} - 3^2P_{\frac{1}{2}}$ were stated to possess a doublet hyperfine structure with separation of about 0·1 cm.$^{-1}$ and intensity ratio about 2 : 1. These results were obtained with a Fabry-Perot etalon. Meanwhile the lines have been investigated with a reflecting echelon of high resolving power in order to detect the presence of weak lines due to the less plentiful isotope. A third very much weaker component was observed; the three observed components being at 0·00, 0·11, and 0·19 cm.$^{-1}$, with ratios 6 : 3 : 1. This structure is the same for both lines of the doublet.

The two strong lines are evidently due to the more plentiful isotope Rb 85, and the weak line is due to Rb 87. But as the ratio of the sum of the intensities of lines due to Rb 85 to the sum of those due to Rb 87 must be about 4 : 1 (the proportion in which the two isotopes are present), Rb 87 must possess an unresolved component of intensity rather greater than 1. This must be obscured by one or other of the Rb 85 lines. It is more probably the stronger line (0·00), as this line appears broadened and somewhat asymmetrical.

On this view, Rb 85 possesses a doublet hyperfine structure with separation of 0·11 cm.$^{-1}$ and intensity ratio slightly less than 6 : 3; the probable value of i, the nuclear spin, being 3/2. Rb 87 also possesses a doublet structure, with separation nearly twice as great, and intensity ratio probably smaller.

It is interesting to note that the lines of the heavier isotope are displaced to the violet. A complete account of this work, with photographs of the fine structure, will appear elsewhere.

Hail Storm, June 14, at Doncaster.

Around my home at Bessacarr, on the Great North Road, three miles E.S.E. of Doncaster, on June 14, at 5 P.M. B.S.T., heavy rain was followed by hail measuring three-quarters of an inch in diameter, then—after a five-minute interval—by hail measuring one and a quarter inches in diameter—with a density of 85 to the square yard. The duration of the second shower was only one minute. Sound elm twigs a quarter of an inch thick were cut off the trees in thousands. The largest stones weighed 20 grams (¾ oz.): twenty per cent showed four growth rings about a white spherical nucleus a quarter of an inch in diameter. The intermediate transparent stages were one-eighth of an inch and the final growth three-eighths. None were angular, but a small number showed a quarter of an inch mosaic allotriomorphic crystallisation on their smooth ovoid surfaces.

A sandpit in the garden was temporarily flooded, and in the thin residual layer of mud the stones made excellent impressions. These were covered by waterproof fabric, and next day, after being sun dried, casts of many of these were taken and a reproduction of the surface made in plaster for the Doncaster Museum.

An Apparatus for Recording the Ultra-Violet Light of the Sky.

In Nature of June 13, p. 893, Dr. J. R. Ashworth describes a photographic apparatus for recording the ultra-violet light of the sky.

It may be doubted whether such a method can give quantitative results, or even relatively correct results on different days, for the following reasons.

First, a step wedge constructed of a diffusing medium, such as thin tissue paper, does not obey the logarithmic 'law', which is valid only for transparent media.

Secondly, photographic paper can be used as a quantitative instrument only by a null method, if any reasonable degree of accuracy is required, since it does not respond in a regular way to light stimulus. For example, equal values of *It* do not necessarily involve equal response by the photographic paper, owing to the existence of the Schwarzchild effect, while the sensitivity of the paper varies according to the atmospheric conditions.

A method which involves a visual estimate of a small change is also open to criticism, since different people have different acuities.

Records of Actinic Value of Daylight.

Records of the actinic value of daylight are being regularly taken in connexion with the 'Jeremiah Horrocks' Observatory, Preston. Strips of sensitised paper carried on a rotating drum pass close behind a narrow slit through which light from the sky enters; the apparatus is set up so that the slit opening is fed with light from an area of the sky 45 degrees square, the centre of the area having an altitude of 45 degrees above the horizon toward the north.

The four records reproduced in Fig. 1 were taken on April 21, 22, 23, and 24 of this year and show the rapid variations of actinic value of diffused daylight. The records are positives, that is, the dark portions indicate absence of actinic light, and the slit width, approximately 0·5 millimetre, provided for an exposure of two minutes.

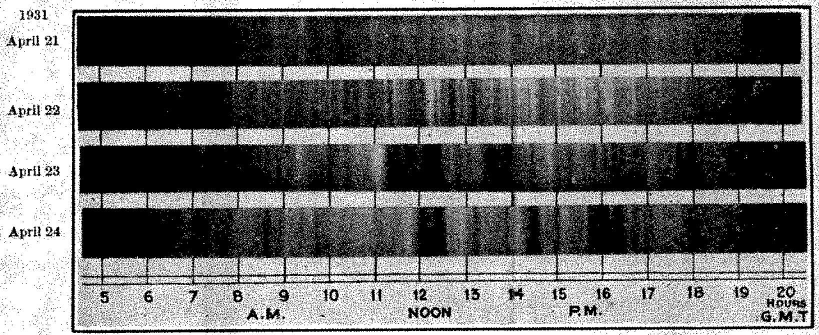

Fig. 1.

Records from three instruments have now been accumulating over a period of many months, and the work is still in progress.

Experiments in Prophylaxis.

The scope of two agents, which are scarcely recognised in an external field, seems to need inquiry.

Creosote rapidly penetrates the skin: it removes the irritation of insect bites (mosquitoes, bugs, harvest-bugs), and then the circulation soon dissipates the swelling. If applied to eruptions at the incipient stage, it dries them, and the foreign matter is imperceptibly exuded. On tender skin it can be diluted with any grease. Will this be equally successful with bites of plague-fleas? What effect would it have on early pustules of small-pox?

Another external germicide is dry sulphate of quinine, which cannot, like iodine, cause serious injury. On an abrasion or cut of blood-vessels it prevents infection and promotes healing; on a badly infected wound I have known it make an entire cure in a week. Solution of quinine will rapidly cure ophthalmia which is resistant to zinc. The scope of such remedies, especially in the tropics, should be determined, as they can be safely entrusted to the ignorant.

Crystal Structure of Molybdenum Trioxide: A Correction.

I regret to say there are two errors in my letter on molybdenum trioxide, published in Nature of Jan. 17. The length c should be 3·67 and not 3·57 A.; and u and v should be interchanged, making $u \sim 30^\circ$, $v \sim 36^\circ$.

Giant Crescents: a New Stone Age Industry from South Africa.—Mr. C. van Riet Lowe describes a new stone age industry from South Africa in the *Trans. of the Royal Society of South Africa*, vol. 19, pt. 3. It consists of an assemblage of stone implements hitherto unrecorded from Mazeppa Bay, at the mouth of the Kogha River, halfway between the Great Kei and Bashee rivers on the Transkeian coast of the Cape Province. The implements are all found on the surface, so that there is no actual evidence of date; but their technique suggests a late Middle [Palæolithic] Stone Age. Material, debris, technique, weathering, show that they belong to a single industry practised from Mazeppa to Algoa Bay and as far inland as the south bank of the Orange River, that is over an area of approximately 20,000 sq. miles. This is a new culture. It is a typical blade-industry, including characteristically long blade-like implements, principally more or less isoscelene (acute angled) in shape and variants of these. Associated with the points, scrapers, and gravers, and by far the most characteristic and interesting product of the industry, is a type of implement only one of which had hitherto been found and recorded in the Union. It is an implement shaped like the quarter of an orange. The flat surfaces meet to form a more or less straight cutting-edge, and there is a strongly curved upper surface away from the cutting edge, coarsely flaked and retaining a portion of the original surface untouched in the middle. The implement may be regarded as a giant crescent. The specimen originally described came from the Kasougu River and was unassociated; but similar and finer specimens are now associated with a definite industry, the present collection coming from Mazeppa Bay. The average size for five specimens is 9·65 cm. by 3·35 cm. by 1·73 cm. Probably the industry represents a transition from the Middle to the Later [Palæolithic] Stone Age, and is an integral part of a cultural admixture from a contact between neanthropic and palæanthropic man.

The Vole Cycle in Britain.—Continuing his study of the fluctuations of voles (*Microtus*) in Britain, A. D. Middleton gives the results of a further series of trapping experiments (*Jour. Ecol.*, vol. 19, p. 190, 1931). As an accurate index of the numbers of voles present in a district the trapping system has proved to be somewhat unreliable, and recourse has been made to the field observations of local reporters. They show that 1930 was a year of uncertain fluctuations, for while in some areas the numbers definitely increased, in others they increased less markedly or even decreased. In some places, therefore, 1929 was a peak year, and in others 1930 seems to be on the way to ushering in another peak year. The conclusion is that the comparatively regular four-year cycle which the author has previously described for British voles is considerably modified by local conditions, and in some areas may not appear at all. The author states that the regular cycle may be evident, or may be quite obscured, according to the favourable or unfavourable nature of the local conditions. But this assumption of favourable or unfavourable local conditions requires proof; the suggestion which the author's vole map makes, since it is founded on more particular observations than were available before, is that even the four-year cycle is a little uncertain in its rotation.

Bovine Tuberculosis and the Pasteurisation of Milk.—The Ministry of Health has issued a memorandum on bovine tuberculosis in man with special reference to infection by milk (*Reps. on Pub. Health and Med. Subjects*, No. 63, London: H.M. Stationery Office, 6*d.* net). A large proportion of tuberculous disease in children less than fifteen years of age is caused by the bovine type of the tubercle bacillus, and it is estimated that more than 1000 children less than fifteen years of age die annually in England and Wales from infection of this origin, which is derived mainly from cow's milk. The proportion of milch cows in Great Britain infected with tuberculosis is probably not less than 40 per cent, of which probably between 1 and 2 per cent yield tuberculous milk. But as market milk is usually the mixed milk of several cows, the proportion of samples of milk containing tubercle bacilli varies in different areas from about 5 per cent to 12·5 per cent. Although much may be done by administrative and other measures to diminish bovine tuberculous disease, complete eradication by tuberculin testing and slaughter of reacting animals, the building up of tuberculosis-free herds, and preventive vaccination, is impracticable. Much may be done by the routine clinical examination of cattle, the testing of milk by microscopic and biological methods, and the keeping of the milch cows under hygienic conditions. The campaign in favour of clean raw milk, as by the use of certified and Grade A milks, while of great potential value, has hitherto met with limited success, probably due largely to the increased cost of such milks. So long as this remains the case, the pasteurisation of milk by retaining it at a temperature of 145° C. for 30 minutes constitutes the best safeguard against bovine tuberculosis derived from milk. The opinion is expressed that pasteurisation carried out in a suitable apparatus and under strict scientific control is capable of protecting the consumer from the danger of infection with the tubercle bacillus, and that milk so treated appears to retain its valuable food properties practically unimpaired.

Biological Research in Hawaii.—Nos. 6, 7, and 10 of Volume 9 of the *Occasional Papers* of the Bernice P. Bishop Museum (Honolulu, Hawaii, 1930) consist of papers by C. H. Edmundson, "New Hawaiian Medusæ", "Effect of Ultraviolet Rays in Regeneration of Chelipeds", and "New Hawaiian Crustacea"; whilst No. 11 is by C. Montague Cooke, jun., and H. E. Crampton on "New Species of *Partula*". The medusæ dealt with belong to the genus *Eleutheria*, which is characterised by the branched tentacles bearing groups of nematocysts or suckers, or both, and having a brood pouch dorsal to the stomach. Many of these medusæ, like the common British form *Eleutheria dichotoma*, creep about by means of their tentacles. Four species new to science are here recorded from Hawaii, chiefly differing from one another and from previously known members of the genus in the position of the clusters of nematocysts and in the margin of the umbrella. They represent the first creeping medusæ to be recorded from the North Pacific Ocean. A new species of *Kishinouyea*, one of the *Stauromedusæ*, is also described. Amongst the Hawaiian crustacea, new species of *Processa*, *Jousseaumea*, and *Axiopsis* are described, and a new genus of the Portunidæ. This new genus *Cœlocarcinus*, containing one new species, has very peculiarly modified fifth legs, having the last two joints developed into rounded foliaceous swimming paddles. The gastropod genus *Partula* is always interesting on account of the geographical distribution of the species, which are, as a rule, each characteristic of certain islands or groups of islands. Four new species are here described—*Partula cytherea* from remote mountain slopes of Tahiti, *Partula lanceolata* from Mango Island in Fiji, 200 to 500 feet, *Partula thurstoni* from Ofu Island, Samoa, and *Partula montana* from the high forest of the Afiamalu region, about 2500 feet, Upolu, Samoa.

A New Parasitic Copepod.—Mr. Isokiti Harada in his paper, "A New Copepod Species Parasitic on Formosan Fresh-water Fishes" ("Studies on the Fresh-water Fauna of Formosa": (1) Contributions from the Zoological Laboratory, Taihoku Imperial University, Formosa, Japan. Journal of the Society of Tropical Agriculture, 2, 71-76, 1930), describes a new ergasilid, which he names *Ergasilus japonicus*, parasitic on the two fishes from Lake Jitsugetasan, Formosa, *Cultriculus kneri* and *Pseudorasbora parva*. All the species of *Ergasilus* hitherto known live upon the gill filaments or within the gill cavities of their hosts, but this one lives on the outside of the body, especially on the mucous membrane at the base of the fins and occasionally on the outer surface of the operculum. None were found on the gill filaments, gill cavities, or elsewhere on the body surface. The cyprinoid fishes *Pararasbora moltrechti* and *Zacco temminckii* were also found to be parasitised by this species. All those on the fishes were females. The males are free-swimming and were collected on several occasions. Free-swimming females were also observed. *Ergasilus japonicus* differs from the other species of the genus in its habitat as well as in the arrangement of the spines and setæ of the legs, in their structure, and in the characteristic flattened swimming plate of the first swimming legs in the female.

A Liverwort as Pioneer on Burnt Forest Land.—Marie Lilienstern has recently attempted to throw some light on the occurrence of *Marchantia polymorpha* as a pioneer plant on burnt-out forest land (*Travaux de la Société des Naturalistes de Léningrad*, vol. 60, livre 3, 1930. Russian with French résumé). Pure culture work shows that *Marchantia* ceases to grow and develops very few gemmæ in the absence of potassium. On the other hand, the cultures show that high concentrations of potassium are not injurious, nor is exposure to guaiacol or pyrogallic acid, which are products of dry distillation of wood and occur in the surface layers of soil in burnt-out forests. *Marchantia* shows a preference for slightly acid conditions, which are also associated with the soil in such localities. It is still a little difficult to gauge the significance of these results without comparative cultures of other liverworts, which do not show any tendency to repopulate burnt forest land. It would be of interest to know whether any similar resistance to relatively high concentrations of potassium and to the presence of distillation products of wood is shown by any of the other plants that one associates with localities where there has been a fire—for example, *Funaria hygrometrica*, *Pyronema confluens*, and *Epilobium angustifolium*.

Irrigation in India.—The review of "Irrigation in India" for 1928-29 (Government of India: Public Works Branch, 2*s*.) gives a statistical and financial summary of the irrigation works in every province of British India. The rainfall in the year under review was on the whole normal, though in the plain areas there was a deficiency of about five per cent, and in the Central Provinces of eleven to twenty-two per cent. The total area irrigated by government works of all kinds was well over thirty million acres, which was nearly three million acres more than in the previous triennium. This total was slightly more than twelve per cent of the total area sown. In Sind it was as high as 90 per cent of the area sown, in the Punjab 30 per cent, and in Bengal as low as 0·3 per cent. Details of the irrigation scheme in project and works in progress are given.

Deep Trench on the North Sea Floor.—In recent surveys of the North Sea the surprising discovery of a trench 130 fathoms deep has been made about 100 miles east of Montrose. The Devil's Pit, as it has been called, is the deepest of a group of depressions found in a floor which was previously supposed to be an undulating plain at 38 to 50 fathoms. Another group of depressions, with a greatest depth of 87 fathoms, occurs farther south, about 65 miles east of Berwick. Prof. J. W. Gregory discusses the nature and significance of these depressions in the *Geographical Journal* for June. He gives reasons for not accepting the suggestion that they have a connexion with the earthquake that was felt in eastern Scotland and southern Norway on January 24, 1927, and he believes that the features are not new but were formerly missed by soundings having been too far apart. Recent soundings in the immediate vicinity of these trenches agree entirely with earlier records of shallow water. Prof. Gregory argues that the trenches are remains of the pre-glacial valley of the Rhine and date from the days when the Rhine and its British tributaries discharged to the North Sea about a hundred miles east of Kinnaird Head. He further points out that the existence of these preglacial trenches adds to the improbability of a Scandinavian ice-sheet having reached the British coast, since it would have filled the trenches with moraine matter. In this case floating ice must have been responsible for the transport of Scandinavian boulders to eastern England.

Long-Range α-Particles.—In the June issue of the *Proceedings of the Royal Society*, Lord Rutherford, F. A. B. Ward, and W. B. Lewis have described an investigation of the long-range α-particles from radium C by one of the new methods. Their results are most illuminating, as they show that, in addition to the well-known group with a normal range in air of 9 cm., there are at least eight other homogeneous groups with ranges between 7 cm. and 12 cm. Their numbers are, however, minute; for every million particles of the common 7 cm. group, there are only seventeen of the most frequent of the long-range groups (9 cm.), and between 0·2 and 1·3 of each of the others. No particles of range greater than 12 cm. were found, and if present, there is certainly less than one-tenth of a per cent of the number in the main set of range 9 cm. In discussing these results, it is pointed out that there must be some intimate connexion between the energy of these long-range particles and the energy of the gamma rays emitted by radium C, and the view is taken that the gamma rays arise from a transition of the α-particle within the nucleus between two different energy-levels. The energies of these levels can be found from the energy of the α-particles, and it is shown that the differences in energy between these levels and the normal level are in several cases in good accord with the energies of some of the stronger gamma rays.

Identification of Hydroxylic Compounds.—Phenylcarbimide has been employed in separating and characterising phenols from tar and tar products and also forms solid compounds with alcohols which have definite melting points. In some cases it can also be used to isolate several dihydric phenols from the aqueous liquors of low-temperature carbonisation, but with the less volatile phenols only oily products are formed. Morgan and Pettet, in the May number of the *Journal of the Chemical Society*, describe a more satisfactory alternative reagent, namely p-xenylcarbimide, the compounds of which, $C_6H_5.C_6H_4.NH.CO_2R$, are considerably less fusible than the corresponding phenylcarbamates, so that phenols which yield only oils with phenylcarbimide provide crystalline p-xenyl derivatives and, in addition, solubility relationships are modified. The paper includes a table of melting points of p-xenylcarbamates and phenylcarbamates, in which compounds formed from several alcohols and phenols appear.

Syntheses of Ethyl Alcohol.—In a paper in the June number of the *Proceedings of the Royal Society*, on ethyl alcohol as a product of high-pressure syntheses, G. T. Morgan and R. Taylor, after reviewing briefly the conflicting results which have been reported in attempts to prepare this substance from carbon monoxide and hydrogen interacting in the presence of catalysts, describe some new experiments which they have performed yielding positive results. The catalyst most used was prepared from cobalt nitrate and zinc permanganate, and the synthesis carried out at 400° and 200 atmospheres, about 75 c.c. of a composite liquid product being obtained per hour. From about four litres of this, the alcohol was separated and identified conclusively by a number of physical and chemical tests. Two acetals have also been separated from the crude products of the catalysis and identified, the more volatile one being ethylidene dimethyl ether, and the less volatile one propylidene dimethyl ether. Six other catalysts are described, each of which was found to induce the formation of appreciable quantities of ethyl alcohol.

Molecular Weight Determinations.—Rast, in 1922, suggested (without reference to the earlier work of Jouniaux in 1912) the use of fused camphor as a cryoscopic solvent, the novelty claimed being that the molecular depression of freezing point for this substance was so large that ordinary melting-point apparatus could be adapted to a micro-method for the determination of molecular weight. The value of the molecular depression constant for camphor was calculated as 400 by Rast from some results on the melting points of mixtures of salol and camphor obtained by Caille, whereas Jouniaux had obtained the higher value 498 from a study of a number of cooling curves of pure substances dissolved in camphor. In the May number of the *Journal of the Chemical Society*, Le Fèvre and Webb show that Caille's results appear to be erroneous, and that the higher value of the constant is to be preferred. They also show that bornyl chloride is a suitable cryoscopic solvent, having the very high constant of about 500. It has a lower melting point than camphor, and is less volatile. The results given are somewhat erratic and great accuracy is not claimed for them, but the method appears to be capable of development.

Astronomical Topics.

Encke's Comet.—Telegrams from Profs. Shapley and Stromgren report the detection of this comet by Mr. Bobone at Cordoba (Argentine), on June 21, at 22 h. 23·2 m. U.T. in R.A. 7 h. 35 m. 24 s., N. Decl. 8° 22′. The R.A. is 56 s. less and the Decl. 44′ less than the values predicted by Matkiewicz; this implies that the time of perihelion is about 18 hours earlier than the predicted value, which was June 3·85 U.T. For most comets this would not be regarded as an unreasonable amount, but this comet has been so carefully studied ever since 1819 that the predictions are usually accurate to an hour. It is too large to be due to Mercury, though a little of it may be due to that planet, if Matkiewicz did not allow for its effect; it was not very far from the comet at the last perihelion passage. Possibly the accelerative effect, which was noted in the last century, but which had nearly died out, has revived again. This is the first detection of a comet for ten months; the cometary nature of the object reported by Prof. Nakamura last November is doubtful.

Calendar Reform.—A Circular from the International Fixed Calendar League reports that the preparatory committee on calendar reform at Geneva has completed its report, which will soon be issued; it will form the basis of discussion at the international conference on the subject, which has been convened by the League of Nations to meet on Oct. 26. Nearly all the schemes of reform include the suggestion that one day in each year (two in leap years) should lie outside the sequence of weekdays, so that every year should begin with the same weekday. There is widespread opposition to this plan, and it is scarcely likely to obtain the support necessary for its universal adoption. The schemes for making the lengths of the months follow a more orderly plan are less controversial; but the reformers are fairly equally divided between the 12-months and 13-months division of the year. The advantage of the latter is the equality of all the months, except for the one extra day. Its chief drawback is that it does not divide into quarters. But it has been pointed out that the case would not be much worse than the present 'quarter-days', which do not all fall on the same day of the month. The discussions next October are likely to be lively.

Improvement in Time-Recording.—The great improvement in clocks, effected by Shortt, calls for a similar improvement in chronographs. Those in general use are limited to hundredths of a second. A paper by Alfred L. Loomis in *M.N.R.A.S.* for March gives a description of a very accurate form of chronograph. A broad sheet of paper is made to advance at a uniform speed past a comb of 100 teeth. The records on the paper are made by electric sparks from these teeth; the teeth are in electric connexion with a disc having 100 teeth, which rotates 10 times per second, so that each tooth corresponds to one-thousandth of a second. The results enable very accurate clock determinations to be made. These show that the maximum clock rate is attained when the pressure in the clock case is between 15 mm. and 25 mm. of mercury. Lowering the pressure from 15 mm. to 1 mm. caused the clock to lose a second a day; this unexpected result is due to the longer swing that occurs with low pressure. A paper immediately following this, by Prof. E. Brown and D. Brouwer, gives an analysis of the clock records extending over several months. The most interesting result is the detection of a small effect due to the moon. The theoretical amplitude is shown to be 0·000153 second, the period being half a lunar day. This is the direct action of the moon on the pendulum, but there are also indirect effects due to the change in the earth's attraction arising from tidal deformation. The analysis of the clock readings gave amplitudes varying from 0·000106 s. to 0·000150 s.; they are, therefore, of the right order for lunar effects. It is hoped that continuation of the observations, using four Shortt clocks, will make it possible to detect changes in the rate of the earth's rotation. The irregularities in the apparent motion of the moon and planets give grounds for believing that such changes occur.

Recent Advances in the Chemistry of the Vitamins.

AT the meeting of the Royal Society held on June 18, the President, Sir Frederick Gowland Hopkins, opened a discussion on the chemistry of the vitamins. He said that although many discoveries had been communicated in the past to the Society, there had been very few papers dealing with the vitamins. He felt great satisfaction that this discussion should occur during the first year of his presidency, especially as the subject was still growing in interest. The Society were to be congratulated on the presence of a number of foreign workers, so that the discussion would have an international character. As the subject was so vast, he proposed to limit it to the chemistry of the vitamins, and suggested that vitamins D, A, and the B complex be taken in that order.

VITAMIN D.

Prof. A. Windaus said that up to the present, investigations had had to be carried out on impure substances and chiefly by means of physical experiments. No stable equilibrium was formed between ergosterol and the products of irradiation. By further irradiation two crystalline substances could be obtained, neither of which could be converted into the other; it appeared therefore that two series of products were formed on irradiation. Reerink and van Wijk had found that no matter whether 10 or 50 per cent of the ergosterol was changed by long wave irradiation, the absorption spectrum of the product was always the same. He suggested that this was due to several substances being formed in constant proportion, and that the absorption spectrum was that of the mixture. None of the products of irradiation are precipitated by digitonin. Failure of precipitation, however, does not imply that a change has taken place in the hydroxyl group. On treatment with phenyl isocyanate the antirachitic activity of the irradiated ergosterol is destroyed. Treatment with warm caustic potash results in the reconversion of the phenyl urethane to vitamin D.

Prof. Windaus had found that the vitamin had the same molecular weight and formula as ergosterol and also contained three double bonds. The dihydro derivative obtained from irradiated ergosterol by treatment with sodium in alcoholic solution was inactive, but it is not certain that it is a derivative of vitamin D itself. The vitamin is more sensitive to a temperature of 180° than ergosterol; after heating, the absorption spectrum shows a band at 2820–2920 A.

Crude vitamin D is stable in oil, although the absorption spectrum and specific rotation rapidly change. The toxicity of the crude product varies with the potency, but it is still possible that the two properties may be due to different substances. The problem has not yet been solved. He had noticed that in vacuum tubes, in which crude vitamin D had been sealed, crystals appeared, but he had not been able to obtain them in a pure state by recrystallisation from cold acetone or by fractional precipitation. He had found, however, that when irradiated ergosterol was treated with maleic or citraconic anhydride in ethereal solution at room temperature for one to three days, a reaction occurred between certain of the substances present and the anhydride. When these inactive products were removed by solution in dilute caustic potash, crystals could be obtained from the ethereal layer on evaporation of the solvent. The yield was 50 per cent of the crude product, or 60–70 per cent of the material which failed to react with maleic anhydride.

Vitamin D crystallises in long needles of melting point 122°; $[a]_D^{18} = +136°$ in acetone, and $[a]_{Hg}^{18} = +168°$ in acetone.

The crystals show a band in the absorption spectrum at 2650–2700 A. Their potency was found to be 2–2½ times that of the M.R.C. standard.

He considered that the product obtained by Reerink and van Wijk was different from his, since it had a lower specific rotation and an absorption spectrum of a different shape, but that Bourdillon's crystals were probably the same. He agreed with the suggestion of the latter that there might be several compounds showing vitamin D activity, but considered that his crystals were responsible at any rate for the chief part of it. Vitamin D is an isomer of ergosterol in which there has been a structural rearrangement with an increase in the spatial size of the molecule.

Prof. B. C. P. Jansen said that Reerink and van Wijk had now obtained crystals of a melting point 140°. Their former product with a lower melting point had contained ether of crystallisation.

Dr. R. B. Bourdillon said that the discovery of the method of obtaining crystals of vitamin D by means of maleic anhydride was of outstanding importance and likely to lead to a solution of the problem of its constitution. He and his co-workers had obtained very similar crystals by distillation of irradiated ergosterol in a high vacuum. Their melting point was 123–125°. The specific rotation to the mercury line in alcoholic solution was +250 to +260°. The maximum absorption occurred at 2700 A. and was greater than that of ergosterol. The potency was 18–22,000 M.R.C. U./mgm., that is approximately the same or slightly less than that shown by Prof. Windaus' crystals. They had been able to prepare an oxalate and acetate and reconvert these back to the original crystals. They had found the rotation and potency to remain constant for some weeks in dry air or in vacuo. Neither by distillation at a temperature of 160° nor by further irradiation with loss of two-thirds of the potency had they been able to separate their crystals into two separate compounds. Moreover, on irradiation the loss of antirachitic activity and the changes in the absorption coefficient and specific rotation were absolutely parallel. They therefore considered that their crystals were a definite chemical compound and had ventured to call it 'Calciferol'. However, the unity of the compound was not absolutely certain, owing to variations in the specific rotation of different preparations. They had recently obtained some crystals with a rotation of +290°. He suggested that there were at least two vitamins, isomorphic and with the same absorption spectra, the lævo form being very unstable, while the dextro form was stable. This suggestion would explain the discrepancies in his own work and that of other observers.

Dr. O. Rosenheim said he considered the work now reported was the most important since the original researches on vitamin D. He thought that Windaus' and Bourdillon's crystals were identical, although it was possible that there might be an impurity present as in Reerink and van Wijk's preparation. Spectroscopic methods had not led to much advance, but success had come from biological and organic chemical research, and especially from Bourdillon's method of fractional condensation. He pointed out that if ergosterol was irradiated until 20 per cent had been changed and the 80 per cent of inactive material removed, the activity of the residue was only the same as that of the original irradiated material. On distillation of the residue, 20 per cent was obtained as crystals, but the activity was only twice that of the crude product.

VITAMIN A.

Prof. H. von Euler said that it was early noticed that fat soluble growth-promoting material was frequently associated with a red or yellow coloration but that the converse was not true. Working with Karrer, he had found that of all red or yellow substances examined, only carotene had vitamin A activity. Carotene was usually supposed to be optically inactive, but he, as well as Rosenheim and Kuhn working independently, had found that it could be fractionated into two forms, one melting at 170° and optically active, and the other melting at 183° and optically inactive. Both forms had growth-promoting power. The latter gave an earlier growth response, but after three weeks the differences between the two disappeared. A dose of 0·003 mg. daily would produce a daily increase in weight of one gram in the rat. Complete hydrogenation of carotene inactivated it, but reduction with aluminium amalgam at first increased the activity. Hydrocarotene containing eight double bonds is much more active than carotene, the daily dose required being only 0.0005 mg. It also gives a higher blue value with the Carr and Price colour test. The absorption spectrum is very similar to that attributed to vitamin A in cod liver oil.

Moore considers that carotene is converted to vitamin A in the body of the rat. Prof. von Euler had tried to effect this conversion in vitro, but only with the serum of the hen had he found that carotene could be converted into a substance very similar to vitamin A although not spectroscopically identical. He considered it probable that the transformation occurs in the blood, and that vitamin A may act as a catalyser in oxidation. He had also examined the anti-infective action of carotene and had found that it did not affect hæmolysis in vitro nor react with amboceptor, but that when it was given in excess to rabbits, the amboceptor in their blood was increased.

Dr. Rosenheim said that carotene is a mixture which has not yet been completely separated, and that it is dangerous to attribute activity to any particular isomer. The optical activities obtained by different observers vary considerably. It is possible that the transformation of carotene into vitamin A in the body may be only the accumulation of vitamin A present as a contaminant in the carotene. The band in the absorption spectrum of cod liver oil at 3280 A. may not be due to vitamin A but to a substance accompanying it.

Dr. R. A. Morton said that if the band at 3280 A. is to be attributed to vitamin A, then the latter cannot be present in carotene as an impurity. Dihydrocarotene is not vitamin A, since the band in its absorption spectrum is at 3170 A., the blue colour given with antimony trichloride is not the same as that given by the vitamin, and the ratio of blue colour to intensity of absorption is different.

VITAMIN B.

Prof. B. C. P. Jansen said that when 100 kgm. of rice polishings were extracted with dilute acid alcohol, 30 kgm. went into solution. By treatment with acid clay it was possible to adsorb nearly all the vitamin B_1, but only 100 grams of contaminating solid material. The vitamin B_1 present accounted for only 1 per cent of the adsorbed material. By fractional precipitation with silver nitrate and baryta it was possible to remove impurities at a strongly acid reaction and to precipitate two-thirds of the vitamin at pH 4–7: above this pH impurities were precipitated as well.

Further purification could be effected by precipitation with phosphotungstic acid, and decomposition of the precipitate with baryta, and precipitation with platinum chloride from alcoholic solution. When the platinum was removed with powdered silver, 1·4 gram was obtained, of which 0·4 gram was pure vitamin. By numerous fractionations with acetone from solution in absolute alcohol, 30 mgm. of pure vitamin were obtained. The formula by analysis was $C_6H_{10}ON_2HCl$. The process he had devised was therefore very wasteful. It could be improved by the use of Peters' method of fractional precipitation with phosphotungstic acid. Prof. Jansen had found that silicotungstic acid was as suitable. When the original 100 grams obtained by adsorption on acid clay were treated with this reagent, two-thirds of the vitamin were precipitated, but only 20 per cent of the total solid. A further improvement had been effected by Seidell's benzoylation process, which removes impurities. By this method von Ween had obtained 140 mgm. of pure vitamin B_1 from 75 kgm. rice polishings.

Prof. A. Seidell said that Prof. Jansen had had success with a method that had failed in his hands. He had felt that precipitating agents ought to be avoided, and so was led to the method of benzoylation in chloroform solution, which removes a considerable amount of nitrogenous material. He had not succeeded in obtaining crystals, although his purest preparation was nearly as active on rats, but when tested on pigeons by Peters' method the activity was found to be only 1/5 to 1/10 that of the crystals.

Prof. R. A. Peters said that he had hoped to be able to use the animal as a test object only and not concern himself with the physiological side of the problem, but he had found that it was only possible to reach a final conclusion on the chemistry when the physiology was also taken into account. He had been able to confirm Prof. Jansen's process up to the platinum chloride stage. Working with yeast he had obtained purification by removal of inactive material with lead acetate and baryta followed by adsorption of the vitamin by charcoal. By fractional precipitation with phosphotungstic acid at pH 5–7, vitamin B_1 was obtained. Its activity was 0·012 mgm. per dose, while that of Prof. Jansen's crystals in his hands was 0·008 mgm. Both preparations gave the Pauly reaction with the same intensity. Miss Reader had shown that 25–50 per cent of Prof Jansen's crystals had vitamin B_4 activity. She had now been able to isolate vitamin B_1 from B_4 by fractional adsorption on to charcoal in the earlier stages of the purification, but the separation of B_4 from B_1 was less complete.

Dr. B. C. Guha said that he had been able to separate B_1 from B_2 by electrodialysis. Vitamin B_1 appeared to be a strong base, while B_2 was a neutral substance.

The President, in summing up the discussion, said that the progress of the last few years should make them optimistic. He expected that we should soon know the constitution of vitamin D. The chemical problems involved were *a priori* difficult, but workers were finding that the compounds were amenable to the methods of organic chemistry. He thanked the visitors from overseas for taking part in the discussion.

University and Educational Intelligence.

CAMBRIDGE.—Dr. C. E. Tilley, of Emmanuel College, has been elected to the professorship of mineralogy and petrology as from October 1.

LEEDS.—The West Yorkshire Coal Owners' Association has offered the University of Leeds an additional grant of nearly £1300 a year for the purpose of financing a scheme of research into industrial fluctuations and other matters, with special reference to their bearing upon the coal-mining and allied industries. The University Council has gratefully accepted this offer, and the work will be carried out under the direction of Prof. J. H. Jones, head of the Department of Economics. The Mining Department of the University has enjoyed a large measure of support from the West Yorkshire Coal Owners' Association, which for some time past has been making a grant in aid of the Department of £1000 a year. The Association was also one of the largest donors to the appeal issued in 1925, its gift of £25,000 being one of the factors which allowed the Mining Department to be dealt with as the first item in the building scheme. The total of the contributions made by the Association to the University exceeds £40,000.

THE Congress of Universities of the Empire, under the presidency of H.R.H. the Prince of Wales, opened in London on July 1. On the first day several educational institutions and medical schools were open for inspection to members of the Congress and there was a special exhibition of educational and cultural films at Bush House. On July 3 the Prince of Wales held a reception and addressed the Congress in the Guildhall. The rest of the time in London was spent in visiting other educational institutions in and around London. On July 6 the Congress proceeds to Edinburgh, where it will remain in session until July 11. On July 7 the Lord Provost of Edinburgh will deliver an address, and in the afternoon there will be a meeting of members of the Universities' Bureau of the British Empire. The Marquess of Linlithgow will address the Congress on July 8, and this will be followed by discussions on the position of the university graduate in commerce and industry, and the standard and conditions of candidature for the degree of Ph.D. in relation to other post-graduate qualifications. The former discussion will be opened by Sir Robert Waley Cohen and the latter by Prof. D. Nichol Smith. On July 9, Lord Meston will give an address and Prof. F. E. Sandbach will open a discussion on the conditions of admission to universities. Later, Prof. W. E. Collinson will open a discussion on the provision of schemes of study leading to general honours degrees. Sir Donald MacAlister, Bart., will address the Congress on July 10. On the same day there will be a discussion on post-graduate study in medicine and surgery in Great Britain, which will be opened by Dr. H. L. Eason, and Sir Thomas Holland will open the last discussion of the Congress on the facilities for overseas students in British universities. Many excursions to places of educational and other interest, also receptions, have been arranged for the entertainment of members.

Birthdays and Research Centres.

July 6, 1873.—Mr. S. G. BROWN, F.R.S., electrical engineer.

I am at present engaged on gyroscopic problems concerned with the sea, land, and air, which have been placed before me by the British and foreign governments. I am always willing to deal with any problems, and in fact I welcome them.

I am also engaged at the moment with acoustical and sound reproduction apparatus, especially in connexion with talking picture equipments and adaptations.

I am convinced that there are still vast fields to be explored where my reed telephone and microphone sound relay can usefully be employed, and I am working on these. My latest invention is the Microbox pick-up, a gramophone pick-up which can be used without employing valves or high power amplifiers. The only energy required can be derived from an ordinary 6-volt battery, and the pick-up can be used with ordinary or portable gramophones and it replaces the ordinary electrical pick-up.

July 8, 1861.—Sir J. ARTHUR THOMSON, formerly Regius professor of natural history in the University of Aberdeen.

Since I retired from my Aberdeen professorship last autumn, I have been completing, with the help of Miss Isobel Dean, a large memoir on the Alcyonacea of the Siboga Expedition. Before I stop this sort of Linnæan work, to which I have devoted so many years, I should like to follow others in giving a general survey of the evolution of the alcyonarians. Along with my teacher and friend Patrick Geddes, I have just completed a somewhat detailed unconventional outline of general biology. But most of all, I am afraid, I have just been enjoying the luxury of doing nothing.

July 9, 1869.—Dr. J. W. MELLOR, F.R.S., principal of the Pottery Department, North Staffordshire Technical College, Stoke-on-Trent, and Director of Research of the British Refractories Research Association.

In the research laboratories, investigations are being conducted under the auspices of the British Refractories Research Association on the nature and properties of the materials employed in the silicate industries; on the nature of the action of industrial furnaces on refractory materials; and on the manufacture of materials best fitted to resist the destructive agencies in the different types of industrial furnaces.

July 10, 1854.—Dr. GEORGE LINDSAY JOHNSON, ophthalmic surgeon to H.M. Forces in Natal.

I am now engaged in completing a large work which has occupied my attention during my spare moments for upwards of forty years, namely, the comparative anatomy and physiology of the vertebrate eye, embracing nearly all available living families and genera of the mammals, reptiles, and amphibians, with references to the eyes of the birds and fishes. Two abstracts of this work have already been published in the *Transactions* of the Royal Society (1901 and 1904), with more than a hundred illustrations in colour and numerous illustrations in black and white on plates and in the text. I hope to have this work published during the current year. My chief reason why its publication has been delayed is due to the great expense of printing the coloured drawings, of which there are more than three hundred.

The practical utility of this work lies in its affording help towards the classification of the Vertebrata, which in a great many instances requires modification. This is especially the case among the families and genera of the rodents. There are still a few animals' eyes to be examined and depicted which I have hitherto been unable to procure or depict. Finally, the optical problems of refraction and accommodation, especially of amphibian mammals, require to be restudied. I would appeal to my colleagues (especially mathematicians and oculists) to assist me in this latter undertaking.

Societies and Academies.

LONDON.

Mineralogical Society, June 9.—**G. E. L. Carter**: On an occurrence of vanadiferous nodules on the coast of South Devon. The author describes an occurrence of vanadiferous nodules in the red marls that underlie the Budleigh Salterton pebble beds on the coast of South Devon. These nodules consist of siliceous and argillaceous material impregnated with vanadium oxide and calcium carbonate. A typical nodule examined at the Imperial Institute showed a roughly concentric structure, ill-defined black shells alternating with shells of light-coloured material. Radiating black bands stood out as ribs on the surface of the nodule. Analyses by Miss Hilda Bennett showed that the black portion of the nodule contained 13·96 per cent of vanadium oxide, estimated as pentoxide. The light-coloured portion of the nodule contained only 1·91 per cent of vanadium oxide, and was relatively richer in calcareous and siliceous matter than the blacker and more vanadiferous portion.—**M. H. Hey**: Studies on the zeolites. Part 2: Thomsonite (including faroelite) and gonnardite. A chemical, optical, and X-ray study of a considerable number of thomsonite specimens has led to the conclusion that thomsonite and faroelite form a continuous isomorphous series. The true symmetry of thomsonite is shown to be didigonal polar (C_{2v}). The unit cell is shown to contain $(Ca,Na)_6(Al,Si)_{20}O_{40} . 12H_2O$. The mean refractive index ranges from 1·517 to 1·535, falling with increase in the Si/Al ratio. Apparatus has been designed and applied to measure the vapour pressure of thomsonite at various temperatures and degrees of dehydration, and it appears very probable that a dimorphous high-temperature form exists, the transition being readily reversible. Gonnardite is probably identical with the high-temperature dimorphous form of thomsonite (meta-thomsonite), and is therefore to be regarded as a separate species.—**A. Russell**: An account of British mineral collectors and dealers in the seventeenth, eighteenth, and nineteenth centuries. A second instalment: John Woodward (1665–1728) and Charles Francis Greville (1749–1809).—**L. J. Spencer**: Hoba (South-West Africa), the largest known meteorite. The large mass of meteoric iron discovered in 1920 on Hoba West farm, 12 miles west of Grootfontein, measures about 10 × 9 feet on its flat upper surface, and is estimated to weigh 60 metric tons. It belongs to the group of nickel-rich ataxites. Chemical analysis by Mr. M. H. Hey shows iron 83·44 per cent, nickel 16·24 per cent, with small amounts of cobalt, copper, sulphur, phosphorus, and carbon. Photomicrographs (× 820) by Dr. J. M. Robertson show a minute plessite-like structure.—**L. J. Spencer**: Twelfth list of new mineral names. Since the publication in 1928 of the eleventh list of this series (the first was in 1897), 120 names have been collected from the current literature. In addition to the bibliographical reference, a brief description of the essential characters of the mineral and derivation of the name are given.—**J. Drugman**: On different habits of fluorite crystals. In fluorite the cube is usually the predominating form. Crystals of other habits—octahedral, rhombic-dodecahedral, and triakis-octahedral—are described. The temperature during the growth of the crystal has perhaps influenced its habit.

EDINBURGH.

Royal Society, June 1.—**H. Briggs**: The relation between the yield of crude oil and the composition of retortable carbonaceous minerals. Using graphical methods, the author showed that, while on the one hand the yield is connected to the percentage of volatile hydrocarbons, and on the other hand to the C/H ratio, these relations are too intangible to be of value. A more definite relation exists between the yield and the percentage of volatiles diminished by twice the oxygen percentage—a conclusion leading to the formula $Y = 0{\cdot}47\ (V - 2O)^{\frac{4}{3}}$, in which Y is the yield of crude oil in British imperial gallons per ton, V the percentage of volatile hydrocarbons, and O the percentage of oxygen in the mineral retorted.—**C. H. O'Donoghue**: Abnormalities of the vascular system of the Anura. One or more striking abnormalities in the blood vascular systems of forty-two specimens of *Rana temporaria* are described. A consideration of the developmental history of the vessels shows that many abnormalities are due to the retention of larval arrangements, and some due to the failure of a portion of the adult system to develop. For others there appears to be no explanation at present available, as, for example, the absence of a precaval vein on one side accompanied by the development of a transverse anastomosis whereby the precaval drainage is transferred to the other side. Connexions between the visceral arteries and veins and the lung find no explanation in the development of vessels or lungs, but analogous vessels to and from the visceral trunks and the swim bladder are found in some Teleostomi. The abnormalities throw a light on the normal relationships of certain vessels in the adult, and often suggest homologies with those of the generalised elasmobranchs.—**G. L. Purser**: The early stages of development of the vertebrates. The only growth-centre is the organiser, the position of which, throughout the phylum, is correlated with the apical pole and a meridian of latitude on the egg which depends upon the amount of yolk. Gastrulation is the formation, under the influence of the organiser, of a meristematic ring, by the proliferation of which the primary germ layers are laid down and growth to any length is made possible. There is no concrescence and the origin of the mesoderm is the same throughout the phylum, except for variations in the head. The evolution of yolkier eggs made it necessary for this ring to be split into a yolk and an embryogenic blastopore, which evolve into the edge of blastoderm and primitive streak respectively. In mammals the homology of all primitive streaks makes the derivation of the trophoblast and Rauber's layer or *Trager* from the yolk-laden cells of lower forms essential. Loss of yolk began in correlation with mammary secretion. Blastula-formation within the confining coats of the zygote is impossible, and the slipping of the cells over one another causes the final enclosure of the apical cells by the abapical ones. The true and false amnia are products of the extra-embryonic cœlom, which allows the expansion of the life-preserving allantois. The 'doubleness' of the endoderm of the blastocyst is due to the absence of yolk and consequent continued extension of the endoderm from the meristematic ring, first seen in the frog.—**Richard Elmhirst**: Studies in the Scottish marine fauna: the Crustacea of the sandy and muddy areas of the tidal zone. A study of quantitative samples from various parts of the coast reveals definite specific zoning in the genera *Bathyporeia* and *Corophium*.

PARIS.

Academy of Sciences, May 11.—**Jean Pierre Robert**: Some properties of *n*-metaharmonic functions.—**J. Dieudonné**: Univalent functions.—**Edouard Callandreau**: The lines of slip of a pulverent mass.—**L. Escande** and **M. Teissié Solier**: The conditions of working of the Pitot tube.—**Georges Marboux**: An electrical oscillator of low frequency stabilised by a tuning fork. The apparatus described and figured is closely analogous with the apparatus using piezo-electric quartz. The tuning fork replaces the quartz. —**M. Auméras** and **A. Tamisier**: The constitution and stability of two copper-nitrogen complexes.—**Dumanois, Mondain-Monval, and Quanquin**: The presence of peroxides in the gases from internal-combustion motors. An experimental proof of the formation of peroxides and of aldehydes under conditions of working of an ordinary internal combustion engine.

Rome.

Royal National Academy of the Lincei, Dec. 7.—**T. Levi-Civita**: Plane sections of a body and orthobaric directrices.—**Enea Bortolotti**: Specialised differential quadratic forms. Ricca's calculus is shown to be easily extensible to these forms.—**F. Conforto**: Metric and foundations of absolute differential calculus in a continuous functional space.—**Miron Nicolesco**: Metaharmonic functions in n variables.—**E. Okhlopkova**: Certain problems on the limits of the theory of logarithmic potential. The theory of the functions of the complex variable is applied to the solution of certain problems of the limits of the theory of logarithmic potential for the circle.—**V. Hlavaty**: The curvature of non-holonomous varieties.—**D. Graffi**: An observation on the equation of the motion of a body of variable mass.—**A. Signorini**: The profile of bridge piers. The variation in kinetic energy between a stream disturbed by bridge piers and the non-disturbed stream is found to be independent of the configuration of the profile of the piers.—**E. Bossa**: Correction to the note on "The Hall effect for the metals, nickel, iron, and copper, in feeble magnetic fields".—**Remo de Fazi** and **Antonio Hemmeler**: Reactions between organic and mineral compounds (1). Natural sulphides and certain acyclic compounds. Pyrites yields (1) ferrous and ferric chlorides, ferrous sulphide, sulphur, carbon, and thiophosgene when treated with carbon tetrachloride at 320°-400° or at 450°; (2) ethyl mercaptan and ethyl sulphide respectively with ethyl alcohol and ether at 450°-500°; (3) thioacetic acid, traces of methyl mercaptan, methyl sulphide, carbon dioxide, hydrogen sulphide, and sulphur with acetic acid at 480°-500°; (4) hydrogen sulphide, carbon and sulphur dioxides, and thioacetic anhydride with acetic anhydride at 450°-480°. Stibine gives carbon disulphide and antimony trichloride when treated with carbon tetrachloride at 300°-325°, and thioacetic anhydride and antimony trichloride when treated with acetyl chloride at 300°-350°.—**A. Mazzucchelli**: Electrolytic deposition of chromium from ammonium chromo-oxalate.—**Carmela Ruiz**: Strophomenides of the Permian of the Sosio basin (Palermo).—**Constantino Gorini**: Acido-proteolytes and thermophiles in the pasteurisation of milk. Experimental results confirm the importance of these organisms in the pasteurisation of milk, and emphasise the necessity of cooling the milk thoroughly immediately after pasteurisation and keeping it cool until it is consumed. Examination for these bacteria furnishes a means of judging of the efficiency of the pasteurisation.—**G. Mezzadroli** and **E. Vareton**: Action of ultra-short electromagnetic waves (2–3 metres) on amylase. These waves exert a favourable effect on the enzymes of seeds, especially on the amylase. When subjected to their action for 30 minutes prior to steeping, barley attains its maximum saccharifying power 0·5–1 day earlier than the untreated control, this period being increased to 2 days if irradiation is continued daily. Moreover, the absolute value of the maximum saccharifying power is increased by as much as 15 per cent.—**D. Cattaneo**: Observations on the structure of the vitreous.—**B. Finzi**: Tuberculin and anæsotuberculin.

Vienna.

Academy of Sciences, Feb. 12.—**E. Haberfelner**: Graptoliths from the Upper Silurian of the Carnic Alps. Part I. Summit, north side.

Feb. 19.—**A. Muller** and **E. Feld**: The thermal decomposition of hydrochloric-1, 6-diamino-*n*-hexane.—**A. Muller** and **E. Feld**: Synthesis of γ-amino-*n*-capronic acid and of α'-ethyl-α-pyrrolidine.—**E. Tschermak**: Some flower anomalies and their mode of inheritance in primulas. Doubling of flowers is common in the plant world, but the formation of a corolla-like calyx, so-called 'calycanthemie', is only known in Primulaceæ and a few other orders. The inheritance of calycanthemie has been studied by crosses between these and normal forms of *Primula acaulis*, *elatior*, and *officinalis*, also by crosses with *P. Juliæ*. In double garden primroses, andrœcium and gynæceum become petaloid, but in double auricula the gynæceum generally remains intact, its doubling concerning the corolla. It is also possible to raise hybrid primulas in which doubling is combined with calycanthemie.—**H. V. Graber**: Report No. 5 on geological and petrographic researches in the Upper Austrian and Bohemian primitive rocks.—**K. Fritsch**: Contributions to the knowledge of the Gesneriaceæ. (3) The inflorescence of *Haberlea rhodopensis*.—**G. Orban**: Radium Institute communication No. 271. Investigations on the natural ionisation of air with the Wilson chamber using alcohol vapour.

Feb. 26.—**A. Tornquist**: The mineralisation phases of the younger east-alpine ore deposits.—**A. Rollett**: The course of esterification with mixed anhydrides and mixtures of anhydrides.—**H. Lieb** and **M. Mladenovic**: Elemic acid from Manila elemi-resin.—**M. Mladenovic** and **H. Lieb**: A new resinic acid from Manila elemi-resin.—**F. Holzl**: Hexacyano-cobaltic-acid and methyl alcohol.—**K. W. F. Kohlrausch**: Additive nature of the atomic chemical combining force.—**F. Werner** and **R. Ebner**: Results of a zoological expedition to Morocco. Two new forms of fish and several previously undescribed Amphibia and Reptilia.—**O. Pongracic**: Contributions to the anatomy of the Gesneriaceæ.

March 5.—**H. Rebel**: The biological significance of societies of larvæ.

March 12.—**M. Kohn** and **S. Fink**: On dichlor-phenols, trichlor-phenols, and their bromination products. Thirty-sixth communication on bromo-phenols. —**M. Kohn** and **L. Steiner**: Brominated hydroquinone and toluhydroquinone ether. Thirty-seventh communication.—**M. Kohn**: Debromination by benzol and aluminium chloride.—**G. Orban**: Radium Institute communication, No. 272. Researches on the radioactivity of the alkali metals by the cloud track method. No activity was detected with cæsium. The β-rays of potassium and rubidium were examined. —**A. Schedler** and **M. Toperczer**: First report on the distribution of declination in Austria at the epoch 1930·0. A new magnetic survey was undertaken in 1928, declination, inclination, and horizontal intensity being measured at more than a hundred evenly distributed points. A table of results is added.

FRIDAY, JULY 3.

GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College), at 7 30 —Dr. W. D. Lang: The Inland Lower Lias of Dorset.—Dr. W. F. Whittard: The Geology of the Ordovician and Valentian Rocks of the Shelve Country, Shropshire

ASSOCIATION OF ECONOMIC BIOLOGISTS (Summer Meeting) (at Farnham House Parasite Laboratory, Farnham Royal).

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children Section) (at Bath).

MONDAY, JULY 6.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Presentation to Dr. Nellie B. Eales of Makdougall-Brisbane Prize.—Dr J. F. V. Phillips, J. D. Scott, and J. Y. Moggridge: Photochemical Measurements of Light-intensity in Two Common Vegetation Types in Tropical Africa, by means of an Improved Eder-Hecht Photometer. (*To be read by title.*)

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

TUESDAY, JULY 7.

ROYAL SOCIETY OF MEDICINE, at 4.30.—Annual General Meeting.

WEDNESDAY, JULY 8.

BRITISH PSYCHOLOGICAL SOCIETY (Æsthetics Section) (at Bedford College), at 5.30.—E. J. Sullivan: The Grotesque in Art.

CONGRESSES.

JUNE 29 TO JULY 4.

INTERNATIONAL CONGRESS OF THE HISTORY OF SCIENCE AND TECHNOLOGY.

Friday, July 3, at 10 A.M. (at Science Museum).—Interdependence of Pure and Applied Science.

Saturday, July 4 (at Oxford).

JUNE 29 TO JULY 4.

CONGRESS OF NAVAL ARCHITECTS (Institution of Naval Architects and Association Technique Maritime et Aéronautique) (at Paris).

Saturday, July 4.—Papers on—
Shipbuilding.
Marine Engineering.
Civil Aviation.

JULY 1 TO 4.

CONGRESS OF UNIVERSITIES OF THE EMPIRE (in London).

Friday, July 3, at 11 A.M. (at Guildhall).—Reception, and Address by H.R.H. the Prince of Wales (President).

Saturday, July 4.—Visits.

JULY 6 TO 11 (IN EDINBURGH).

Tuesday, July 7, at 10.30 A M.—Address by the Lord Provost of Edinburgh.

Wednesday, July 8, at 10.30 A.M.—Address by the Marquess of Linlithgow.
At 11 A M.—Sir Robert Waley Cohen and others: Discussion on The University Graduate in Commerce and Industry.
Prof. D. Nicol Smith and others: Discussion on The Standard and the Conditions of Candidature for Ph.D. in relation to other Post-graduate Qualifications.

Thursday, July 9, at 10.30 A.M.—Address by Lord Meston.
At 11 A.M.—Prof. F. E. Sandbach and others: Discussion on Conditions of Admission to Universities and their Effects.
Prof. W. E. Collinson and others: Discussion on The Provision of Schemes of Study leading to General Honours Degrees.

Friday, July 10, at 10.30 A.M.—Address by Sir Donald Macalister, Bart.
At 11 A.M.—Dr. H. L Eason and others: Discussion on Post-graduate Study in Medicine and Surgery in Great Britain.
Sir Thomas H. Holland and others: Discussion on Facilities for Overseas Students in British Universities.

Saturday, July 11.—Visits.

JULY 4 TO 11.

ROYAL SANITARY INSTITUTE (at Glasgow).—Subjects for Discussion:—
The Rôle of the Hospital Relative to the Development of Preventive Medicine.
The Proposals of the British Medical Association for a General Medical Service, from the Standpoint of Preventive Medicine, and in Relation to National Health Insurance.
Development of the National Health Insurance Scheme.
Administration of the Local Government Act, 1929.
Eugenic Sterilisation.
Health Certificates before Marriage.
Pregnancy and Tuberculosis.
Maternity and Child Welfare Work.

JULY 6 TO 11.

CONFERENCE OF MUSEUMS ASSOCIATION (at Plymouth).

Monday, July 6, at 5.15 P.M. and 8 P.M.

Tuesday, July 7, at 10 A.M.—Official Welcome by the Mayor.
At 10.20 A.M.—Sir Henry A. Miers: Presidential Address.
At 11.5 A.M.—Lt.-Col. J. M. Mitchell: Address.
At 11.45 A M.—Discussion.
At 12 noon.—Councillor J. Bailey: The 1924 and 1931 Loans Acts.
At 3 P.M.—A. J. Caddie: Plymouth Porcelain.

Wednesday, July 8, at 9.30 A.M.—W. G. Constable: The Courtauld Institute of Art.
At 10.15 A.M.—S. C. Kaines Smith: Art Museum Problems.
At 11 A.M.—K. de B. Codrington: A Suggested System of Museum Registration.
At 11.45 A.M.—Dr. L. J Spencer: Paper for Museum Labels.
At 6 P M.—Meetings of Regional Federations.

Thursday, July 9, at 9 30 A.M.—Annual Business Meeting.
At 11.30 A.M.—Dr. W. T. Calman: Taxonomy in the Museum.
At 12.15 P.M.—H. J. M. Maltby: Present Day Problems of Provincial Museums
At 2.30 P.M.—Dr. E. J. Allen: The Preservation of Marine Life, Wet or Dry Specimens.

Friday, July 10, at 9.30 A.M.—Prof. J H. Iliffe: Museum Problems in Canada.
At 10.15 A.M.—Dr. H. Murray: A Simple Way to Test Museum Value.
At 11 30 A.M.—F Loney: Why do we use Plate Glass in Museums?

Saturday, July 11.—Excursions.

JULY 9.

BRITISH ELECTRO-FARMING CONFERENCE (at Royal Agricultural Show, Warwick), at 3.—M. M. Harvey: Electricity on the Farm, including Dairy and Poultry Farming.

JULY 9 AND 10.

OPHTHALMOLOGICAL CONGRESS (at Oxford).

Thursday, June 9.—Symposium:—L. Paton, Sir Percy Sargent, Dr. H. M. Traquair, N. Dott, and Prof. A. Schuller: The Diagnosis of Intracranial New Growths.
Prof. G. Elliot Smith: The Evolution of the Instruments of Vision (Address).

Friday, June 10.—Dr. Baillart: Tonometry.
P. Adams: An Ophthalmological Mélange (Doyne Memorial Lecture).
J. Craig and Prof. Schuller: Discussion on Penetrating Wounds of the Eye.

GENERAL MEETING.

JULY 8 TO 10.

INSTITUTION OF MINING ENGINEERS (at Manchester).

Wednesday, July 8, at 11 A M. (at College of Technology).
Dr. T. D. Jones and C. E. Morgan: The Candle-powers of Safety-lamps before and after Underground Shifts.
Prof. W. H. McMillan: Comparative Photometric Tests of Miners' Electric Hand Lamps.
Prof. R. V. Wheeler and D. W. Woodhead: The Flame Safety-lamp: The Use of Reflectors.
Discussion on The Problem of Lighting in and about Mines.
At 2.15.—Prof. H. Briggs: History of the Coal-oil Industry.
R. Faulkner: Roof Control in the Arley Seam, No. 1 Pit.

Thursday, July 9, and *Friday, July* 10.—Visits.

EXHIBITION.

JULY 6 TO 25.

EXHIBITION OF CANAANITE AND HYKSOS ANTIQUITIES (at University College, London).

Editorial and Publishing Offices:

British Chemical Industry.

DURING the past hundred and fifty years or less, scientific method in general and chemical research in particular have gradually invaded the industrial arena. Some of the results of this invasion are patent even to the least initiated, whilst others are accepted without a thought of their origin. Popular interest in scientific research is a thing of recent development; it is only in quite recent years that science, even industrial science, has been 'news', but there is now no lack at least of lip service to the part which it plays in industrial prosperity, as well as in providing the minor needs and newer comforts of everyday life. A few casual preparations excepted, chemical manufacture scarcely existed at the close of the eighteenth century; fifty years ago it was still but an apprentice in the world's workshop. Now it is one of the great fundamental businesses of the civilised world, and one which plays a large part in the maintenance of Britain's industrial, and therefore political, equilibrium. The industry is peculiarly one which depends for its very existence on discovery and invention; it is born in the test tube and nurtured on the laboratory bench in universities and in the research departments maintained by the State and by industrial concerns. It is an industry which demands continuous improvement in its methods, and offers unlimited opportunities of development and expansion; it cannot stand still, but must ever move forward along the paths mapped for it by an army of trained investigators.

Chemical industry is not, of course, exempt from the operation of the so-called laws of economics, and in the present period of world-wide depression it shares in the common suffering; how far the state of the market may be attributed to overproduction, to irrational or antiquated technique, or even to fundamental defects in our commercial methods or in our social system itself, must remain for the present a subject for study and discussion. Nevertheless, reports of progress assure us that the chemical industries are, on the whole, affected less than others, and that this circumstance is largely owing to the astonishing technical progress which is being made in every direction. It may also be due—in fact, it can scarcely fail to be due in some measure—to the familiarity of the directors of such concerns with the results accruing from the daily application of scientific methods of research and control, and to their determination to apply similar methods to management and salesmanship. The customer has to be studied no less critically than the process;

and to preach co-operation while ignoring the advantages of standardisation is to invite a well-founded charge of inconsistency. Standardisation is a word which, rightly, assails our social and artistic feelings, but in industry it is a potent economiser and an efficient lubricant; the attention which it is now receiving—exemplified by the formation of a new Standards Association which includes the chemical industries—is therefore a matter of surprise only in respect of its somewhat tardy appearance. In another report on applied chemistry we read that " in spite of the world-wide depression in the iron and steel industries . . . much attention has been devoted to improvements . . . and modifications . . .", whilst from yet another we learn that " the experience of the oil-seed, fatty oil, and allied industries has proved no exception to this general phenomenon [of depression, loss, and unemployment]. . . . These industries, however, owe much of their present strength to the extent to which rationalisation has proceeded in them, commercial foresight having made much use of scientific discovery and technical development."

One reason, evidently, for the citizen's new interest in scientific discovery and invention, and therefore in scientific education, is to be sought in a realisation of the close connexion between the acquisition of new knowledge and the stability of his own economic position; at the same time he may fairly be credited with an increasing interest in the knowledge itself, an interest which deepens as his own education widens. He will shortly have an opportunity of displaying that interest, and of surveying the circumstances in which the chemical industries have reached the position which they now occupy in Britain. This year the Society of Chemical Industry celebrates the fiftieth anniversary of its foundation. A scientific society fifty years old does not now rank as juvenile, yet how short a period is fifty years in a nation's life! As a contribution to the jubilee celebrations, Dr. Stephen Miall, editor of *Chemistry and Industry*, has written an account * of the development of chemical manufacture in Great Britain. For reasons which we have examined, his book will be regarded by many intelligent, although not scientific, people as one of the more important publications of recent years; scientific people will welcome it as a noteworthy work of reference which is unique in its authority and scope. Dr. Miall has accomplished a task of some difficulty, for until 1882 there was no journal devoted to British chemical industry, and, moreover, there were few books that attempted to describe the progress of any considerable parts of the industry. By combining the advantage of personal contact with its leaders with the goodwill shown by members for an object undertaken by their society, he has received a great mass of valuable information which otherwise might, in a few years, have been irretrievably lost; it is this fact, no less than the attractive manner of presentation, which recommends his story to chemists and non-chemists alike.

It might be thought that the manufacture of 'heavy' chemicals, such as alkali and sulphuric acid, is at least a simple, self-contained, and established process which offers little bait to the pioneer; yet we learn how complex it has become, how one part is dependent on others, and " almost every effort to prevent waste involved the manufacture of some new product ". Unfamiliar names and unsuspected associations will whet the curiosity of the student of chemistry: Josias Christopher Gamble, who, like Joseph Priestley, was a minister of religion and devoted much attention to chemical experiment, became a manufacturer of bleaching powder, alum, sulphuric acid, and Glauber's salt; whilst Walter Weldon's fame is reputed to be shared by the history of bleaching and of ladies' fashions.

Economists tell us that prices depend on the gold output; Dr. Miall observes that the increase from about seven million ounces in 1887 to about twenty million ounces now is largely due to the invention of the cyanide extraction process by a chemist named MacArthur and two brothers, Glasgow medical men, named Forrest. It is obvious that material success will always be dependent on business acumen as well as on technical advance, and this subject is discussed in the chapter on the dyestuffs industry in relation to the acknowledged supremacy of the German dye industry during the forty years or so preceding the War. The reasons which Dr. Miall advances are concerned with the patent laws, with the lack of import duties, with relative business ability, with selling organisation, with inadequate opportunities for the publication of new discoveries, with our lack of chemical engineers, and with the fact that in the late 'sixties and early 'seventies there were far greater facilities for learning organic chemistry in Germany than in England. This reason is regarded as almost sufficient without any others, and its prominence is a striking commentary on the anxiety with which professors of organic chemistry in Great Britain recently regarded a proposal—since fortunately postponed—to remove certain importation restrictions on dyes. Their knowledge of the history of the dyestuffs industry in Great Britain and of the intimate relation which subsists between the work of the universities and the future of this and allied industries aroused justifiable fears that organic chemistry itself, and with it the vitality of the dependent industries, would suffer severe damage by premature removal of that protection.

---

* A History of the British Chemical Industry: Written for the Society of Chemical Industry on the Occasion of the Fiftieth Anniversary of its Foundation. By Stephen Miall. Pp. xvi+273+35 plates. (London: Ernest Benn, Ltd., 1931). 10*s*. 6*d*. net.

Abounding evidence is presented by Dr. Miall of the generous way in which successful industrialists have endowed the prosecution of scientific researches; the results have proved not merely a source of profit and a means of increasing employment, but also a source of inestimable material benefit to the human race. In some instances the endowment has taken the form of financial aid to existing research departments of academic institutions and of the creation of fellowships for the support of investigators; in others, of the foundation of new centres of research. A notable example of the latter form of service to humanity is to be found in the enterprises of the Wellcome Foundation, Ltd. These include a Bureau of Scientific Research, an Entomological Field Laboratory, a Museum of Medical Science, Tropical Medicine, and Hygiene, Physiological Research Laboratories, Chemical Research Laboratories, and a Historical Medical Museum. Thus a firm engaged in the manufacture of drugs and fine chemicals seeks to promote progress in the discovery, manufacture, and use of new and important means for the alleviation of human ills.

This outlook, this conception of social duty, is typical of a number of members of the British chemical industry, and the nation has reason to be grateful for the public spirit which is thus demonstrated; they will not be grudged the commercial advantages which their policy affords, and their example will be commended to other industrial firms in a position to do likewise. It may be true, as Dr. Miall says, that the man of business pursues money, the man of science pursues truth, and the man who attempts to do both is handicapped in each direction; the shrewd observation can scarcely be claimed to apply to co-operative effort by men of business associated with men of science. The former know that truth pays, and the latter nowadays at least escape the fate of Leblanc or Lavoisier. Moreover, fickle chance may smile upon them, as it did upon Caro's (but not upon Perkin's) alizarin patent, or upon Perkin's failure to synthesise quinine, or upon Spence's basin of alum. But accidents and failures are, on the whole, best avoided. A hundred years ago, Prof. Thomas Thomson published a history of chemistry which is still read with pleasure and profit by students of chemical science. "Let the sciences advance for another century", he wrote in 1831, "with the same rapidity that it has done for the last fifty years, and it will produce effects upon society of which the present race can form no adequate idea." In 1931 Dr. Miall writes: "Chemical research and technical research proceed in a manner which is satisfactory, and the skill of our chemists and chemical engineers is such that they can cope with all the demands of the industry. We may be confident, notwithstanding present difficulties, that there will be enormous advances during the next twenty years in the application of science to industry, and that much of this advance will be due to chemists." In a foreword, Sir Harry McGowan declares that "To be worthy of our fathers is to surpass them". What will be the historian's verdict in 2031?

Electron Diffraction.

The Wave Mechanics of Free Electrons. By Prof. G. P. Thomson. (The George Fisher Baker Non-resident Lectureship in Chemistry at Cornell University, Vol. 8.) Pp. v+172. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 12*s.* 6*d.* net.

ALTHOUGH de Broglie's first suggestion that moving particles might be accompanied by a wave system was based primarily on the consideration of free electrons, the first development of the wave mechanics, subsequent to the advance made by Schrödinger, was largely concerned with stationary states of bound electrons and their immediate properties, such as their energies and the possibilities of transitions between them. This is not surprising, since any system of atomic mechanics must at least account for the existence of stationary states and their properties, and Schrödinger's development occurred at a time when the limitations of the orbital quantum theory, after its initial successes in this field, were becoming seriously felt.

Though its success in these applications was the first physical justification for the concept of waves accompanying moving particles, they are primarily theoretical, and to follow them in detail often demands considerable mathematical equipment. They appear somewhat sophisticated, and a physicist might well ask for some simpler and more direct evidence for the waves before taking them seriously and endowing them with some sort of physical reality. Such direct evidence is provided by the diffraction and interference phenomena shown by electron beams, which form the subject of the book under review and which its author was one of the first to study. Here he provides an eminently readable account of the experimental material and relevant theory, the balance being more on the experimental side than in most books on wave mechanics.

In the account of the experimental evidence, the author has kept strictly to his title, and only considered the phenomena shown by electrons. The pioneer experiments of Davisson and Germer on the diffraction of electron beams by crystals, the author's own work, and that of Rupp and of Kikuchi are clearly and carefully discussed, with a certain amount of technical detail which should be useful to others working on similar lines, and other work is referred to more shortly.

In the final chapter are considered some applications of the phenomena of electron diffraction, mainly to the study of surface films on solids. Among the differences between X-rays and electrons as tools for the investigation of the structure of matter are the smaller penetrating power of the electron beam and the much smaller amount of matter required to give a diffracted beam of electrons of photographable intensity; and these properties make the electron beam particularly valuable for the investigation of surface effects. It seems likely that many other applications of this tool of physical research will be found in the next few years, and some may well come to have technological importance.

As well as the experiments on diffraction, for which the results are very definite and the interpretation clear and simple, an account is given of those on refraction and polarisation, for which neither the results nor their interpretation are so definite.

The account of the experimental evidence on the diffraction of electron beams is preceded by an introductory chapter in which the antithesis between wave and particle properties and the dual nature of light and electrons are clearly put, and by three chapters dealing with the properties of waves in general, their diffraction by a space lattice, and a preliminary formulation of wave mechanics.

Following the account of the diffraction experiments come two chapters on the effect of refraction on the diffraction of electrons by crystals, and the intensity of scattering of electrons, considered mainly experimentally, with references to the theory; then follow two chapters on the theoretical interpretation of the phenomena, and one on the magnetic electron.

The interpretation of wave mechanics is a subject on which it is notoriously difficult to obtain complete agreement, and while recommending Prof. Thomson's theoretical discussions, the reviewer cannot agree with him at all points. One of the fundamental questions is the physical interpretation of the wave function ψ, which seems to merit closer discussion than it is given, in view of its central position in wave mechanics as a physical theory. Schrödinger's interpretation of $|\psi|^2$ as electron density is adopted at first, without a suggestion of its limitations, and the transition to Born's probability interpretation seems to be made rather casually; the more general validity of the latter would have been strongly emphasised by an example, such as that of partial transmission and partial reflection of a wave packet at a potential discontinuity, in which the interpretation in terms of electron density does not hold.

The application of wave mechanics to a system containing many interacting particles is only considered very shortly, but seems to have a very close bearing on the physical significance of wave mechanics, as in general it is found to be quite essential to consider the wave representing the whole system as a wave in co-ordinate space, and not as a superposition in ordinary space of the waves of the separate particles (although the latter may sometimes be useful as an approximation). If the wave of one electron is given a physical reality, this can scarcely be denied to the wave of a two-electron system; but this means giving a physical reality to co-ordinate space, which most physicists probably regard as a purely mathematical concept.

This suggests one answer to a question asked by Prof. Thomson, "What is the medium which transmits electron waves?" But even without this argument we might reply, "For what is a medium wanted?" Surely by now we have a more general concept of a wave than one which needs a displaceable medium as "a nominative of the verb 'to undulate'". Even a sound wave can be regarded primarily as the propagation of a pressure variation (which happens to be accompanied by a displacement), and if we speak of a wave of epidemic sweeping across a country (as we could do accurately, not only figuratively), we mean that the measure of the incidence of the disease varies in a particular way, and there is no suggestion of displacement of a medium in this case. Even the treatment of light waves which pictures them as due to displacements of an 'ether', implies a 'sub-ether' to provide a frame of reference for the displacements of the 'ether', and Prof. Thomson rightly objects to sub-ethers.

All who are interested in wave mechanics as a physical theory, and not only as a field for mathematical exercise, will find this book of interest and value, and stimulating in its discussion of points on which divergence of opinion is still possible. Among others, those who are making their first acquaintance with wave mechanics will find it valuable. In an introductory presentation, we may either follow the historical development, which may tend to upset the balance of the subject by unduly emphasising the stationary states, or we may start with the diffraction and interference phenomena of electron beams as established experimental facts and develop the theory from them. There is little doubt that the latter will usually be found the more convincing, and for this reason particularly we welcome a book in which the experimental evidence for these phenomena is collected and considered in detail, and especially one such as the present, in which theory and experiment are so well blended. D. R. HARTREE.

Auto-frettage, and the Theory of Strain.

War Office. Overstrain of Metals: and its Application to the Auto-Frettage Process of Cylinder and Gun Construction. By Major A. E. Macrae. Pp. ix + 378. (London: H.M. Stationery Office, 1930.) 21*s.* net.

BETWEEN 1840 and 1850, Rodman, in the United States, investigated a new method of casting thick iron cylinders. He cooled the bore so that the inside hardened first. The outside, cooling afterwards, contracted and thereby placed the cylinder wall in a state of stress, compressive on the inside, tensile on the outside. Further work was done forty years later by Kalakoutsky in Russia, by Prof. Perry at the beginning of the present century, and by M. Malaval during and since the War; the modern method of achieving the same result being to expand a forged steel cylinder hydraulically into the yield range, so that on release of pressure the permanent set of the interior places the exterior in elastic stress. Major Macrae now gives us a very complete record of the work done at Woolwich on this subject. Written mainly for gun-makers, this book should be of interest and value also to engineers in general, who will find therein a vast fund of experimental data on the testing of metals under both tensile and compressive loads up to and exceeding the elastic limit, and on the most suitable heat treatment to restore elasticity that has been lost by overstrain.

No time is wasted by the author on the work of his predecessors, no doubt justifiably; but there is a notable omission in Chap. iv. from the list of hypotheses which determine the criterion of failure of a metal. No mention is made of the 'strain-energy' theory propounded by Prof. James Thomson. The derived relation, $T^2+P^2+2\sigma TP=E^2$, is not so convenient to work with as that of the shear theory, giving in its simplest form $T+P=E$, which fortunately appears to give good results up to a point, but it might have been included in such a general review.

The first two chapters are mainly concerned with definitions and a review of some accepted principles. Chap. iii. contains the results, both tabulated and diagrammatic, of the principal preliminary experiments on the overstraining of steels, gun-metal, and manganese-bronze, and on the most suitable heat treatment to be applied after the process. The results are well arranged, and it is in this chapter that the civil engineer will find most of the 'meat'. Chap. iv. is devoted to steel cylinders under elastic strains; Chap. v. to the theory and practice of the new 'auto-frettage' method of gun construction. The argument of this chapter, particularly at the beginning, is very well and clearly built up. The experimental results on which the theory is based are extremely well set out in a series of diagrams.

Of the mathematical treatment it is not possible to be so enthusiastic. The arithmetical development is laborious, frequently redundant, and not always strictly logical. The classical theory of elastic stresses in a cylinder is revised, and at first sight there appears to be a proof (on p. 124) of the assumption, usually specified, that longitudinal stress is constant throughout a section of a tube. The apparent proof rests on the finding that $T-P=\text{constant}$; but the fact that $T-P$ is constant is inherent in the two differential equations:

$$\frac{d(PR)}{dR}=-T, \quad . \quad . \quad . \quad (2)$$

and

$$\frac{d(TR)}{dR}=-P. \quad . \quad . \quad . \quad (3)$$

Where does (3) come from? The equation before (2) on p. 123, from which it purports to come, gives (2) but not (3). Actually (3) is only correct if it is already assumed that $T-P=\text{constant}$. In other words, this assumption is tacitly made, though not stated, when equation (3) is inserted, and the equation is then used to prove the assumption that has already been made.

The development of the shear theory that is used considers stresses in two dimensions only, though in the majority of cylinders (gun tubes included) there are stresses in three dimensions. The author, on p. 137, advances an argument for neglecting longitudinal stress, but here he is not very convincing. There is evidently a need for a more general treatment of the theory.

A very convenient assumption made throughout the book is that the cross-sectional area of a cylinder remains constant during strain. But a word of caution is necessary. "By the Conservation of Volume . . ." is written on p. 201, much as if it were a principle analogous to the conservation of energy. As a principle it should, it is thought, be regarded with considerable reserve. The experimental evidence is interesting. Some figures support the assumption; others do not. On p. 275 it is wrong by 1½ per cent and on p. 279 by 5 per cent. Yet it is an extremely useful assumption to make, and it is hard to see how we can get along without it.

The last three chapters are devoted to problems that mainly concern the gun-maker. To him, the book is full (perhaps too full) of formulæ designed to give an answer to every numerical question that is likely to arise in his work. It is easy to criticise such a book: by a stringent revision of its mathematics there is no doubt that a considerable saving of space would have resulted, together with a great increase in readability. Classification and headings of sections, and indexing also, leave something to be desired. But as a record of an immense amount of careful and organised labour during years of experiment and research; to the engineer for its copious experimental results; and to the scientific worker for its unexplained curiosities—such as the bending in of the recovery curve before the stress on a test piece has been fully released (shown in the pull-push diagrams in Chap. iii.); the change in stress without change in strain after the application of heat (section F, Chap. v.); or the significant similarity between the cyclic curves in Chap. ii., and the *BH* curves obtained in finding magnetic hysteresis loss —it is a valuable contribution to that foundational fringe by which we are approaching a new aspect of scientific knowledge. To refer only to one parallel investigation—Herbert's recent work on the remarkable hardening properties of a metal when rotated in a magnetic field (*Proc. Roy. Soc.*, vol. A, 130, No. 814)—it is evident that a new line of inquiry requires attention. The question which all this subject brings so insistently before us is: Why do the atoms of a metal cling together at all? What really are the forces that oppose strain? Why, in fact, is a metal a metal, and not, for example, a gas?

Major Macrae's book is written for engineers and is not directly concerned with questions of this kind. But it is an important work, with which everyone interested in these matters should make himself familiar.

Indian Ethnography.

The Mysore Tribes and Castes. By the late H. V. Nanjundayya and Rao Bahadur L. K. Ananthakrishna Iyer. (Published under the auspices of the Mysore University.) Vol. 3. Pp. viii + 619 + 76 plates. (Mysore: Government Oriental Library; Bangalore: Government Book Depot, 1930.) 12.8 rupees.

THOSE interested in Indian ethnography will welcome the appearance, after an interval of twelve months, of vol. 3 of the Mysore Survey Records, carrying the reader from C to K. The volume opens with a somewhat lengthy article on Christians (Roman Catholic and Protestant), which might clearly have been very considerably curtailed. In a work such as this, which deals primarily with tribes and castes, any attempt to convey the essentials of the Christian creed and ritual seems at first sight a little out of place. We are given parts of the marriage service, and certain well-known prayers which are obviously available elsewhere; whereas, a detailed description of such caste distinctions as the Roman Catholic Church has thought it wise to tolerate as a concession to the engrained prejudices of converts is unfortunately not to be found. In Goa and the adjacent Portuguese territory, it has been found that three classes, Brahman, Charado (that is, Kshattriya), and Sudra Christians, remain as an indication of the converts' former Hindu status. We should have been interested to learn whether, in Mysore, the caste distinctions permitted, as indicated on p. 56, take a similar or a more detailed form.

The student, however, will find in the rest of the volume much that will amply repay the effort of careful study. Unquestionably, one of the most valuable additions to our present knowledge of the castes of Southern India is the admirable tables on pp. 579-582 giving details of the exogamous divisions of the trading caste known as Komatis or Shettis. According to the author of the article on Komati, these traders style themselves Vaishyas, claim to have come to Mysore from Ayodhya, and to have been divided into 102 exogamous *gotras*. These *gotras*, as the writer points out, are really totemistic divisions named for the most part after well-known trees, plants, fruits, and flowers. We recognise at once the *Rui* (*Calotropis gigantea*) and the *Shami* (*Prosopis spicigera*) which apparently constitute the totems of the Kausika and Valmiki *gotras*. A comparison of the 101 entries in his list with the well-known *devaks* of the Marathas and kindred tribes in the Deccan discloses a remarkable series of coincidences, and is therefore of no little importance.

We are informed (p. 542) that the use of the article known as the totem is eschewed; and that when there is any doubt concerning the correct totem for a subdivision, it is usual to fall back on the screw-pine (*Pandanus odoratissimus*), itself a well-known totem in the Deccan and elsewhere, which they must abstain from using.

In Indian ethnology, it is well known that the lower the status of the tribe or caste dealt with, the more usual it is to find marriage regulated by totemistic divisions, and the larger the number of articles embraced by such totem lists. It is particularly noteworthy that Komatis, as we have found in the case of the Marathas in the Bombay Presidency, still possess so much evidence of a primitive origin.

As was to be expected, we find in this volume a good list of similar divisions among the Holeyas, a low caste of scavengers and dealers in horns and hides. Reference should also be made to the articles on Gollas, Halepaiks, Helavas, and Kadu Gollas by those interested in further lists of totemistic divisions. The lists would have been more valuable if the writer could have supplied, in each case, the botanical name of the tree or plant referred to, in order to assist identification and comparison with the contents of other lists. On pp. 169-174 and on pp. 540-541 will be found a list of words used by Dombars and Komatis that may be of interest to philologists. Many of them seem, at first sight, to be mere corruptions of other and well-known forms of the same words.

An interesting sidelight on primitive customs is furnished by the note on p. 168 under the article on Dombars, a wandering tribe of acrobats and tumblers. It appears that it is considered a great sin among Dombars to kill a cat; but that this offence can be washed away by eating the cat afterwards! This seems a very simple way of avoiding the wrath of the cat-godling involved.

There is so much good material in this volume that a critic is disposed to restrict adverse comment to a minimum. But a few such comments seem called for. The cross-references in the case of synonyms and subdivisions have again been omitted. It is understood that this defect will be made good when vol. 1 is finally published: but such cross-references ought to be in alphabetical sequence in each volume, to be of real value to the student.

Misprints are undesirably frequent; on p. 518, footnote, "Tile" for "Title" makes nonsense of a translation of the Kanarese word *biradu*; on p. 580, "Hilly Basil" scarcely suggests the "Holy Basil" (*Ocymum sanctum*), for which it seems to be intended. The name of the writer of this review has been spelt in three different ways, and we again find the late superintendent of the Ethnographical Survey of the Central Provinces unfairly referred to repeatedly as Russel. The illustrations are in many cases excellent; but here again a little more care in correcting the spelling would have been useful. *Kare okkalus* are black cultivators (corresponding to Kala Kunbis in Marathi); *Kara okkalu* does not convey the same meaning. The tailor caste, which is the subject of an excellent article, appears as Dārzi in the text and Darji in the illustrations. Such small blemishes are surely both avoidable and unnecessary.

However, we may genuinely offer our congratulations to the compiler on the progress that is being made with the publication of these valuable records; and we shall await the two remaining volumes with much interest. R. E. E.

Short Reviews.

Instinct and Intuition: a Study in Mental Duality. By G. B. Dibblee. Pp. 394. (London: Faber and Faber, Ltd., 1929.) 25*s*. net.

MR. DIBBLEE was led into researches into the nature of intelligence, instinct, and intuition by his previous work on the "Psychology of Supply and Demand and of Economic Value". His conviction that demand is dependent upon value, and that value is determined by "plain human unreasoning instinct" rather than by intelligent judgments, made him desire to understand more about the psychological process underlying human reasoning and what he calls extra consciousness, as well as about its physiological basis.

According to Mr. Dibblee there are, physiologically speaking, two areas of intelligence in man. There exists "an instinctive intelligent faculty, lying on the physiological side of our central faculty of conscious reason, and . . . an intuitive faculty, lying on the intellectual side, a partner, in fact, of the intellect, but outside the limits of conscious operation". The seat of the first is in the thalamus, that of the second in the cortex. He thus breaks away from Lloyd Morgan, who finds the seat of human intelligence mainly, if not solely, in the cortical area.

Mr. Dibblee is not afraid of frankly metaphysical hypotheses—nay, prophecies. He believes in the coming of telepathy: "We shall recognise as a commonplace fact, that unknown vibrations and waves are passing between individuals all the time. The method of physically tuning waves and vibrations, so as to be serviceable in personal communications, will no doubt be becoming as much a branch of psychology as now it is to study the internal mechanism of the eye or the ear." Whether this horrible prophecy will come true is, fortunately, not certain, as most physicists would agree. We should obviously be deprived of the last resort of privacy, morals, and decency, and life itself would become intolerable.

In the last paragraph of the book, Mr. Dibblee tells us that "the parallel capacity in our intuitive faculty brings us extra-consciously into intimate relations with minds or a mind quite probably very different from our own". Thus the book will no doubt be taken up by the metaphysical schools of thought in our modern culture, and if the argument be physiologically sound, it certainly provides a charter for a new psychology of religious revelation.

Exploring for Plants. By David Fairchild. From Notes of the Allison Vincent Armour Expeditions for the United States Department of Agriculture, 1925, 1926 and 1927. Pp. xx + 591. (New York: The Macmillan Co., 1930.) 21*s.* net.

THE author of this work is the head of the Foreign Plant Introduction Service of the U.S. Department of Agriculture. To deserve his attention, plants must have at least some political economic value, though he delights in the charm of the settings where his subjects occur. Every effort must concentrate on the introduction and establishment of the plant within the United States; all standards and comparisons are by American values. It is given to few to be allowed to indulge their fancies; Dr. Fairchild had a unique opportunity to follow his hobby and the work in which he delights, thanks to the assistance of Mr. Allison V. Armour and his yacht the *Utowana*. His party visited the Canaries and Mediterranean countries, parts of Malay, and West Africa.

"Exploring for Plants" is the record of the expert economic botanist, who recounts, with the freshness of first impressions, the plants and plant products he observed and collected, the food, peoples, and customs of the countries visited, and the vicissitudes of the three expeditions. There was little that escaped the keen eye of Dr. Fairchild, and toll was levied of every plant bearing seed, in the hope of being able to establish it in some part of the United States.

The book is profusely illustrated with pictures, but the only maps are two line blocks tucked away towards the end. The author is an experienced traveller, and on the far eastern tour he, unfortunately, had several opportunities of proving his conviction that one must be ill in a foreign country in order to know what the civilisation of that country is like.

The Elements of Analytical Geometry. By J. I. Craig. Vol. 1: *Straight Line and Circle.* Pp. xiv + 415. (London: Macmillan and Co., Ltd., 1930.) 12*s.* 6*d.*

IT is not often that the writer of a mathematical book is privileged to have such a varied experience as the author of this volume. Mr. Craig declares in the preface that he has been called upon to "deal with questions in fields as diverse as Celestial Mechanics, Sport, Geodesy, Hydrography, Meteorology, Ballistics, Census, Agriculture, Food Supply, Statistics, Pensions, Public Health, and Currency Theory". In all these, he pays a tribute to the value of the mathematical habit of thought, in general, and to the practical utility of analysis applied to geometry, in particular. The course embodied in the book is the immediate outcome of lectures delivered at the Royal School of Engineering, Cairo, and these are based to a large extent on a long experience in the application of analytical geometry to the solution of practical problems. The straight line and circle form the subject matter of this first volume, and the treatment is not only full—trilinear and tangential co-ordinates and vector equations of the circle being included—but also, as might be anticipated, is characterised by numerous practical applications. Amongst these, such interesting topics as railway curves, circular nomograms, and sound-ranging are excellently dealt with. Whilst, however, the book certainly has a practical bias, the theoretical side is not only well covered, but also appears to be mathematically sound. The volume, which has also been translated into Arabic, should be very useful, especially to the engineering student who desires more than a superficial knowledge of analytical geometry.

Chemische Thermodynamik: Einführung in die Lehre von den chemischen Affinitäten und Gleichgewichten. Von Prof. Dr. Hermann Ulich. Pp. xvi + 353. (Dresden und Leipzig: Theodor Steinkopff, 1930.) 18·50 gold marks.

IT is a pity that some universal agreement cannot be attained in the symbolism employed in thermodynamics. Prof. Ulich in this volume on chemical thermodynamics uses symbols which differ from those employed by Nernst, Gibbs, and G. N. Lewis, and thus does not subscribe to either a European or an American standard. This defect is to some extent mitigated by the fact that a compilation of the thermodynamic symbols employed by different authors is given in the introduction. Many books on chemical thermodynamics are inclined to stress the purely mathematical treatment, without bringing the significance of the various equations home to the physical chemical reader by examples. This volume may be commended, in that numerous applications of the three laws are given. It is agreeable to find entropy tables both for elements and compounds now included in a text-book on thermodynamics, as well as exemplification of the practical utility of Gibbs's chemical potential function μ. The last chapter in the book, on surface phenomena, is the least satisfactory; but in the others the reader will find much of interest and of value. E. K. R.

Development of the Hudson Bay Region and the North-West Territories of Canada.

By DR. BRYSSON CUNNINGHAM.

THE romance of the mythical 'North-West Passage' which inspired the hopes and fascinated the imaginations of the pioneer navigators of the sixteenth century and their successors for several generations thereafter, has had a curious and interesting sequel of recent years, culminating, after some hesitations and two changes of programme, in the approaching completion of a new commercial port and harbour on the western coast of Hudson Bay, forming the terminal of a branch railway line from the Winnipeg-Prince Albert section of the Canadian National Railways, and the contemplated inauguration of a regular service of steamers through Hudson Strait to the North Atlantic Ocean. No longer is the extravagant and visionary idea entertained of a new sea route from Europe to India; in its place has arisen a much more rational and feasible project for the effective development of the spacious and, at present, sparsely occupied regions lying in Manitoba, Saskatchewan, and the great North-West Territories of the Dominion, and the systematic exploitation of their enormous wealth of natural resources, by providing them with a direct outlet to the ocean highways of the world.

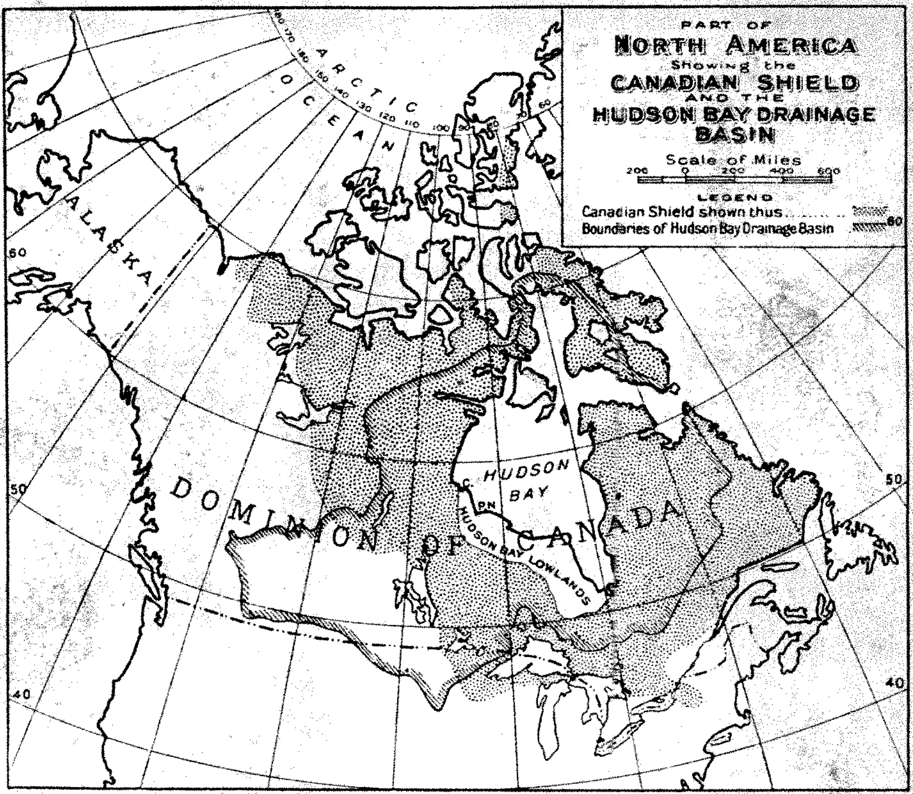

FIG. 1.—Churchill and Port Nelson, on the shores of Hudson Bay, are indicated by C. and P.N. respectively. From "The Hudson Bay Region", by F. H. Kitto, issued by the Department of the Interior and the Natural Resources Intelligence Service, Ottawa.

The vast inland sea, with an area of well over half a million square miles, called Hudson Bay after the famous navigator, penetrates far and deep into the North American Continent (see Fig. 1), and were it not that the sole avenue of communication with the outer Atlantic lies through a region so far north (within 5° of the Arctic Circle, in fact) as to be blockaded for the greater part of the year by a formidable and impassable barrier of ice, it would be a network of busy trade routes, since its waters lap a coast-line fully as extensive as the entire Atlantic seaboard of the United States. Unfortunately, too, Hudson Bay, which is fairly deep in itself, except along some parts of its south-western shore, is lacking in serviceable natural harbours. On the western and southern coasts (excluding James Bay, which is quite shallow) there are only two inlets which afford any pretensions to shelter and anchorage for vessels of modern draught. These are Nelson and Churchill, situated at the mouths of rivers bearing the same names.

The harbour of Nelson, however, is scarcely more than an open roadstead; it is exposed, shallow, and difficult of approach. Despite the fact that a terminal at Churchill would involve a longer railway line and the consequent drawback of a correspondingly longer haul for traffic, the authorities decided at the outset in its favour, and work was commenced in 1911 on the new branch line, with Churchill as its objective, on a route entirely north of the Nelson River, which measured 474 miles in length from the junction at The Pas with the existing line. For some reason, however, the impression gained ground that the constructional difficulties of a line to Churchill would be considerable and even prohibitive, and before much progress had been made, this consideration, combined with the economical question of haulage, caused the Government to alter its plans and to locate the railway with the view of an approach to Nelson. This change enabled the route to be shortened by 50 miles, and the line was actually laid for a distance of 332 miles as far as Kettle Rapids (Fig. 2), where the river Nelson is crossed for the second time, the first occasion being at Manitou Rapids. At this stage of progress, the War intervened and operations were suspended.

It was not until 1926 that work was actively resumed, and then the whole question of the rival merits of Nelson and Churchill as prospective port terminals came up for reconsideration. A special Committee of the Senate recommended that expert advice from a leading authority on harbour development should be obtained, with the result that Mr. F. Palmer (now Sir Frederick Palmer) was commissioned by the Government to investigate the position and report. Mr. Palmer's conclusions were formulated in the autumn of 1927. He had no difficulty in deciding that, on all the evidence, the balance of advantages as a port terminal is definitely and unmistakably on the side of Churchill. Moreover, the constructional difficulties of the land route were found to have been greatly over-stated, and it was ascertained that it would be no more difficult to construct a line of railway to Churchill than to Nelson, the only drawback being that the distance is 87 miles greater.

The cost of the longer line, however, could be more than compensated by the saving in artificial harbour protection works. For, as regards protected harbourage, Churchill presents features indubitably more favourable than those of Nelson. The former port has an easy approach from deep water to a sheltered situation, with ample draught for the requirements of modern shipping. "At Churchill", states Mr. Palmer's report,[1] "Nature has provided magnificent breakwaters, consisting of rocky cliffs rising to heights of from 40 to 70 feet, enclosing a harbour 6 miles in length and from 1 to 2½ miles in width at low water and 1½ to 4 miles at high water. The entrance to the harbour consists of a narrow gap between these headlands, with a low water width of 1600 ft., a width of 850 ft. at 30 ft. depth, and 750 ft. of width having depths exceeding 60 ft. Inside the entrance there exists an area of 140 acres with depths of 30 ft. and over at low water, and a further area of about 180 acres with depths varying from 18 to 30 ft. at low water, beyond which there is a vast area of lesser depth."

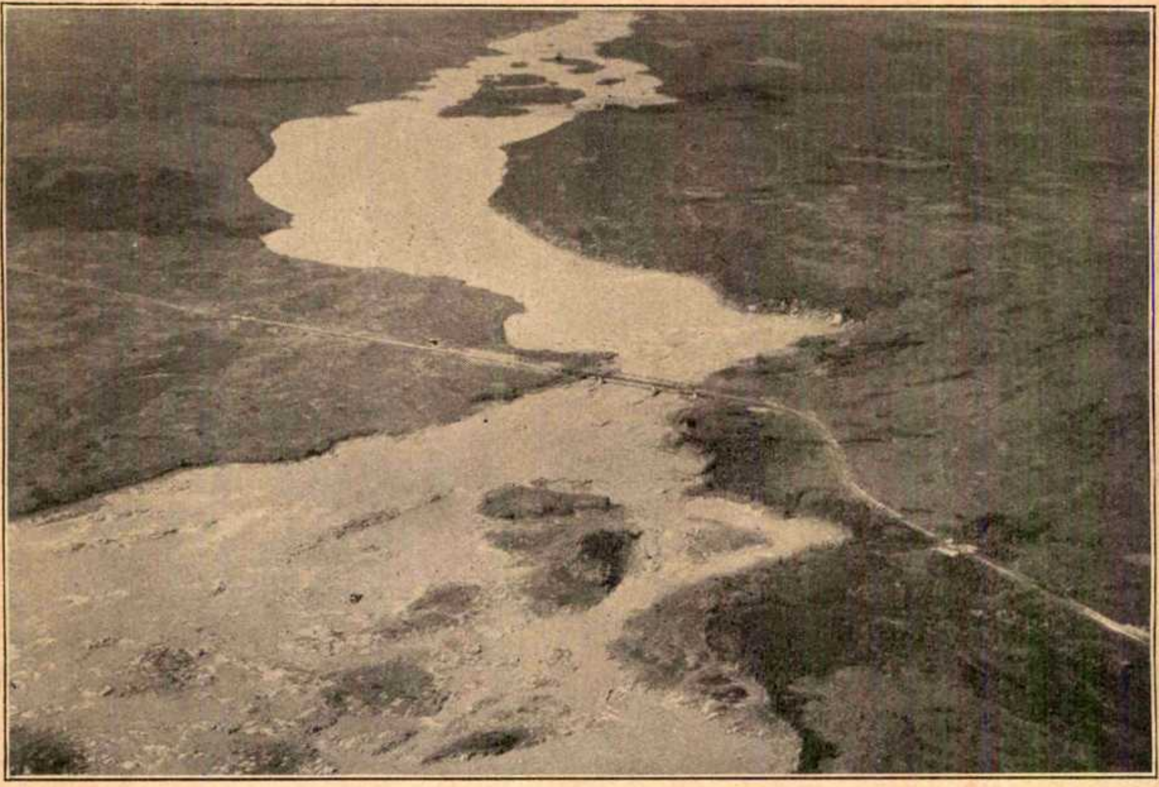

FIG. 2.—View of Kettle Rapids, Nelson River, showing the railway line and crossing. By courtesy of the High Commissioner of Canada.

The Government promptly acquiesced in the findings of this Report, and since that date it has been energetically pursuing the realisation of the project, which, as stated earlier, is now within reach. The site of the wharves and terminal is shown in Fig. 3. The port is expected to be fully open for traffic in 1932, and it is hoped that an experimental shipment of grain will be made during the summer season of this year.

The great problem (and the one uncertain factor in the case) is the question of ice. The sole seaward approach to the new port will be through Hudson Strait and the navigability of this passage is only practicable during a season of very restricted extent. As soon as the decision was finally made to adopt Churchill as the strategic point of sea contact, steps were taken to study the environment and navigable channels of the Strait, and an aerial expedition was sent out by the Department of Marine and Fisheries, which established itself for observational purposes on three bases at points on Hudson Strait. The reconnaissance extended from the spring of 1927 to the autumn of 1928, covering two navigational seasons. The report of Capt. N. B. McLean, the officer in charge, cautiously indicates the duration of free navigational movement as about four months in the year. "Taking July 19 as an opening date for the Strait, and November 16, when ice was first reported at Nottingham in 1927, as a closing date, we get a season of 120 days, or practically four months, during which commercial vessels could have navigated with safety and without the assistance of ice-breakers. It must, however, be borne in mind that data obtained during two seasons only is entirely insufficient on which to base any accurate statement in regard to the opening, closing, or length of the season of navigation." [2]

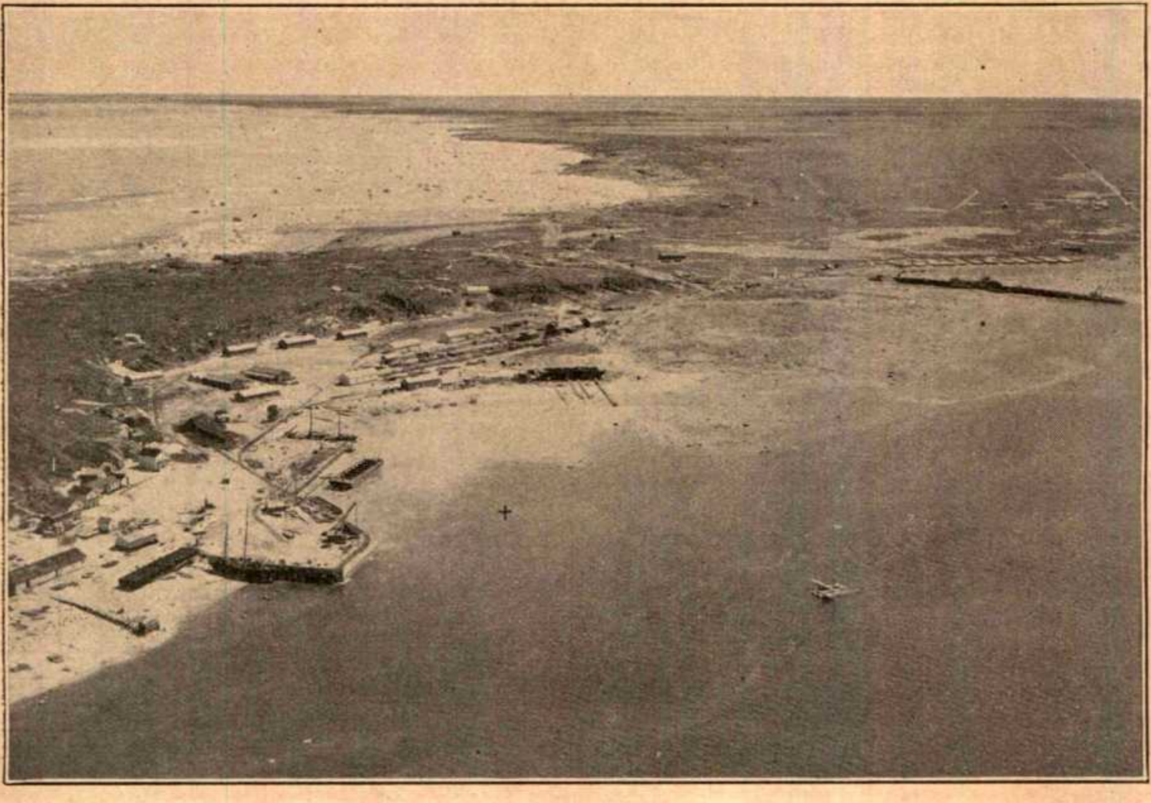

FIG. 3.—View of Churchill Harbour, looking east, and showing the site of the new port terminal. By courtesy of the High Commissioner of Canada.

The navigational period is obviously very restricted, and the prospect of any appreciable extension by modern ice-breaking operations is not altogether too promising, but, on the other hand, it must be remembered that much can be done by intensive seasonal working. Montreal is a port similarly handicapped in regard to ice conditions, though perhaps not quite to the same extent, yet in a short summer season of about seven months no less than 200 million bushels of grain have been shipped and dispatched to Europe. Careful organisation and capable working may lead to correspondingly effective results at Churchill.

Should the experience of the new route prove satisfactory and its commercial feasibility be confirmed, the prospects of developing the almost illimitable hinterland behind the Bay are very alluring. The harvests and agricultural products of the western provinces have hitherto reached the British market either by way of the Great Lakes and the ports of eastern Canada or, alternatively, by the Pacific ports and through the Panama Canal. To Liverpool, the distance from Edmonton or Calgary by the latter route is between 10,000 and 11,000 miles, and by the former about 5200 miles. The Hudson Bay route will mean a further saving of practically a thousand miles.

Apart from the abundant crops of grain and cereals for which Manitoba, Saskatchewan, and Alberta are renowned, there are numerous fields of exploitation in other directions in a region rich in natural resources of many kinds. Trapping for furs has long been an established feature, and the Hudson Bay Company, formed so long ago as the year 1670 under the governorship of Prince Rupert, nephew of King Charles I., has carried on a prosperous trade for more than two centuries. The rivers teem with fish. Water power is plentiful and invites conversion at numerous falls into electricity for adaptation to various industries. Forests in the southern areas provide an abundance of timber, with the promise of extensive supplies of pulpwood for paper manufacture, in addition to the considerable number of trees available for constructional and commercial purposes.

Not less remarkable is the scope for mining minerals and precious metals. The great pre-Cambrian area covering very nearly the whole of the Hudson Bay region, and known as the Canadian Shield, has given startling evidence of being one of the world's largest storehouses of mineral wealth. The famous Hollinger mine is third among the largest gold producers in both hemispheres. There are impressive copper-zinc ore deposits in northern Manitoba and massive bodies of ferriferous ore on the Belcher Islands in Hudson Bay.

The country is still largely in the exploratory stage, and much of its wealth yet remains to be discovered. From such evidence as has accumulated to date, it is clear that there is every ground for believing that the internal resources of the Hudson Bay region will prove highly remunerative and profitable to the capable prospector. The opening of the new route to Europe will afford a means of facilitating the initiation of further enterprise, and will doubtless lead to a great era of commercial, industrial, and agricultural development in the inland provinces of western Canada.

Modern Whaling.

SO far as historical records show, whaling was first begun in the twelfth century by the Biscayans in the Bay of Biscay. From that time until the beginning of the present century, all whaling stations were situated on land.

Towards the end of the nineteenth century, Svend Foyn had tried to operate a floating factory, but the venture failed. The next attempt in this direction was made by Commander Christensen when, in 1903, he sent a wooden steamer fitted as a temporary factory and accompanied by two attendant catchers to Svalbard (Spitsbergen). So much success attended this expedition that Christensen afterwards bought the steel steamer *Admiralen* and fitted her out as the first fully equipped floating factory. This proved to be an epoch-making vessel. In 1925 she was sent to South Georgia, accompanied by two catchers, and from that date the great modern Antarctic whaling era may be said to have begun. There are now one Argentine, three British, and four Norwegian companies operating at South Georgia, and seven Norwegian companies at South Shetland, in addition to various other shore and pelagic factories working elsewhere in the Antarctic.

Prior to the outbreak of the War, some twenty-four steamers had been converted into whaling factories, but all worked in or near harbours, depending—in part at least—upon water and other supplies from the shore. Since the War about the same number of ships have been converted, but the majority of the latter are designed to work in open seas entirely independent of any shore base. The pioneer in this field of development was the renowned whaler, Capt. C. A. Larsen.

Until roughly five years ago, all the working up of whales was done in the water alongside the factory ships, the blanket of blubber and severed pieces of the carcass being hoisted on board by winches and derricks. To avoid the labour and discomfort involved in such a trying and uneconomical method, by means of some kind of slipway which would enable the entire carcass to be hauled on board, had long been the dream of many a whaleman. Numerous suggestions were put forward and a number of ships fitted with various types of slipway. These were located in different parts of the vessels—from bow to quarter—but not one proved satisfactory. Not until the introduction of a *straight* slipway through the *stern* was success eventually achieved. The great obstacle in the way of a straight slip was the profound respect with which all sailors regard the stern frame and rudder post of a ship.

In 1925 the "Globus" Company bought the s.s. *Flackwell* (now *Lancing*) for conversion into a pelagic whaler. Mr. Chr. Fred Christensen, in cooperation with Capt. H. G. Melsom, supervised the reconstruction of this ship. With commendable courage they decided to make drastic alterations and arranged a straight and permanent slipway down to the waterline *through the stern*—a process which necessitated the cutting away of about eleven feet of rudder stock and stern frame post.

This revolutionary design proved highly successful, and has formed the model for all subsequent slipways. Improvements quickly followed until what the designers consider full efficiency was attained in the *Vikingen*—a new ship designed and built specially as a pelagic whaling factory at Messrs. Swan, Hunter and Wigham Richardson's Wallsend shipyard in 1928.

In a very valuable and intensely interesting handbook* just published, Mr. Christensen describes this ship. Plans of the vessel are given, along with detailed information regarding the arrangement of the machinery and plant on board and the methods of working them. Photographs of the *Vikingen* and of her catchers at work are also included. To this are added a brief outline of the history of whaling and an account of various important modifications and improvements in whaling operations.

---

* The Whaling Factory Ship *Vikingen*, with some Notes on Whaling. By Chr. Fred Christensen. (Newcastle-on-Tyne: North-East Coast Institution of Engineers and Shipbuilders, 1931.) Pp. 24 + 2 plates. n.p.

Mention is also made of the immense value of the whaling industry both to Norway and Great Britain. Since 1928, new factory ships totalling 140,000 tons and costing £2,500,000 have been built, excluding catchers. In addition to these new vessels, the whaling companies have bought in Great Britain about 250,000 tons of steamers for conversion into factories and transports. The approximate figures of expenditure in Great Britain during this period are:

Steamers converted into factories	£1,000,000
Floating factories (new buildings)	2,500,000
Transport ships for factories	950,000
Repairs to all types of vessels	550,000
Whale catchers (new buildings)	2,200,000
Total	£7,200,000

In addition to the above, the purchase of coal, oil, and equipment in Great Britain has amounted to millions of pounds, and the British Government derives a large income from licences and duties paid by the companies on the oil and guano they produce.

G. A. S.

Obituary.

DR. LOUIS DOLLO.

DR. LOUIS DOLLO, who died at Brussels on April 19, will always be remembered for his numerous and valuable contributions to our knowledge of extinct vertebrate animals. Early in 1882 he was appointed assistant-naturalist in the Royal Museum of Natural History, Brussels, where he afterwards became conservator, and was actively engaged in research until his retirement in November 1925. He arranged and labelled the unique collection of Belgian fossil vertebrates in the new museum which was opened in the Leopold Park in 1905, and he published preliminary descriptions especially of the fossil reptiles in a series of remarkable papers, besides preparing a general guide-book to the vertebrates, both living and fossil.

Dollo was born at Lille on Dec. 7, 1857, and completed his education in the university of that city, where he graduated as a civil engineer. He studied geology under Prof. J. Gosselet, and he also devoted much attention to the zoological sciences both at Lille and in the marine biological station at Wimereux, under the direction of Prof. A. Giard. His inclination was towards natural history, and he abandoned an engineering career as soon as the opportunity for biological research presented itself in the appointment at Brussels in 1882. His early training, however, influenced him throughout life, and nearly all his writings are in the peculiarly mathematical form of brief numbered statements and proofs.

In the Brussels Museum, Dollo began immediately to study the fossil reptiles, and his first paper, published in October 1882, was a description of *Mosasaurus* and a new allied genus, *Pterycollasaurus*. The finest specimens of Mosasaurians in Europe were found in the Upper Cretaceous rocks of Belgium, and Dollo in subsequent years made many contributions to our knowledge of these extinct sea reptiles. In 1882, however, much progress had already been made in extracting from the rock the wonderful skeletons of Iguanodon and other reptiles which had been discovered four years previously in the Wealden of Bernissart, near Mons. Dollo was then entrusted with the study of this collection, and he soon produced a series of "Notes" in the Museum bulletin which described whole skeletons of Iguanodon for the first time, made known many new facts, and discussed them in a brilliant manner. He also published notes on the associated crocodiles and turtles, and the oldest known newt. These papers were intended to be preliminary to an exhaustive monograph on the whole collection which he hoped to prepare, but difficulties arose which unfortunately prevented the accomplishment of the task. Dollo, indeed, was forbidden by the director of the Museum at the time to proceed with his researches on fossil reptiles, and was ordered to pay attention to the fishes. Thus originated his classic paper on the evolution of the Dipnoi, and many other suggestive papers on evolutionary problems which made fundamental advances in the methods of studying fossils. He established the general principle that during evolution "an organism never returns exactly to its former state even if it finds itself placed again in circumstances identical with those through which it has passed". He described this as the irreversibility of evolution, and it is sometimes termed Dollo's law. He also emphasised the importance of 'ethology', or the study of organisms in relation to their natural surroundings, and furnished many striking examples in his later papers. His last paper, on the carpus and tarsus, published in 1929, fully maintained his old standards, and was written in the characteristic logical form.

Dollo had many ardent admirers among contemporary biologists, and a distinguished group of his friends made contributions to the first volume of a new serial *Palæobiologica* which was published by Prof. O. Abel in Vienna in 1928 in honour of his seventieth birthday. He was a foreign member of the Linnean, Geological, and Zoological Societies of London, and was awarded the Murchison Medal of the Geological Society in 1912. He was also an honorary Sc.D. of Cambridge. He was professor in the University of Brussels, and member of the Royal Belgian Academy. He was also a corresponding member of the Academies of Science of Berlin, Munich, and New York. He was an acknowledged leader, with a devoted following in the new generation.

A. S. W.

LIEUT.-COL. H. T. MORSHEAD, D.S.O., R.E.

ON May 17, Col. Morshead, of the Survey of India, was shot dead while riding in the jungle near Maymyo, the hill-station of Burma. He was forty-eight years of age, and his death deprives the Government of India and its Survey Department of an officer whose special attainments and rare experience had proved of frequent advantage.

To the north of India lies the mountain mass of Tibet: its people belong to the Mongolian family, but they have been shut off by their mountains from the outer world for many centuries, and they have developed a language that differs from both Chinese and Burmese.

Col. Morshead was a skilled mountain surveyor and a Tibetan linguist; and his boyish, modest charm of manner won for him the friendly confidence of Himalayan hill-tribes. The value of such a man has been great, and the discoveries which he made have led to scientific advances in Himalayan geography.

In 1901, when he was nineteen years of age, Morshead passed out of Woolwich Academy and received a commission in the Royal Engineers. In 1904 he was ordered to India, and was posted to Dehra Dun: he was there employed on the designs and construction of new lines for the Gurkha Regiment. Dehra Dun is a cantonment situated in the outer Himalayas, and when Morshead found himself surrounded by mountain peaks, the instincts born in him were stirred. An office of the Survey of India is at Dehra Dun, and Morshead, though modestly doubtful of his own qualifications, began to envy his brother officers who were employed on the Survey. His inclinations were towards exploring, and the idea of taking theodolite observations from hill summits seemed to him a glorious prospect. He was posted to the Survey of India in 1906, and except for the three years 1915 to 1918, when he served in the trenches in France, his whole career from 1906 to 1931 was passed in the Survey.

In 1912 the Himalayan peak of Namcha Barwa was discovered by Captains Morshead and Oakes. This discovery was the most important advance that had been made in Himalayan geography since the height of the Kashmir peak Nanga Parbah was determined in 1855. No high snow peak had been found by the Survey in the Assam Himalaya east of Bhutan. In 1880 the Surveyor-General of India had come to the conclusion that the Assam Himalaya carried no peaks above 20,000 feet. The height of Namcha Barwa is 25,455 feet; like Mount Everest, it is not visible from the plains of India, being concealed by intervening hills. Its discovery has led to the prolongation of the Great Himalayan crest-line for 300 miles.

In 1913, Capt. Morshead and Capt. F. M. Bailey discovered the gorge where the Tsangpo river, of Tibet, escapes from the highland through the Himalayan range.

In 1921, the Mount Everest expedition was organised by the Royal Geographical Society and by the Alpine Club. Col. Howard Bury was in command of the expedition, and Morshead was attached to it as a surveyor. His knowledge of the Tibetan language proved of great service on this expedition. An authority on the Tibetan language had been led to believe that the six names for Mount Everest and its surrounding peaks were recorded in a book of Tibetan ritual, and he was confirmed in this view by Tibetans from the district. But Morshead when in the field with the Mount Everest expedition had learnt from local Tibetans the six Tibetan names of the peaks of Gaurisankar, which are thirty-six miles from Mount Everest. When the names from the book of ritual came to be compared with Morshead's names obtained by him from the people on the spot, it was found that the book of ritual had been incorrect in applying these names to Mount Everest.

When we are looking back upon an officer's career, we recall his scientific achievements. But now that Col. Morshead has been suddenly cut down in all the vigour and activity of middle age, the thoughts of his brother officers turn not to his successes, great as they were. The sorrow which they feel for his widow and children, to whom he was so devotedly attached, fills their minds, and leads them even to forget for the moment the services he rendered to geography. S. B.

MR. HERBERT TOMLINSON, F.R.S.

THE death on June 12 of Mr. Herbert Tomlinson will bring to the minds of many of our older physicists the kind of work that engaged the attention of the research workers of the late Victorian days. Mr. Tomlinson was born in 1845 and went to St. Peter's School, York, from which he gained a scholarship at Christ Church, Oxford, where he studied mathematics and physics, receiving the B.A. degree in 1868. This appears to have completed his connexion with Oxford, for he never took his M.A. degree.

Shortly after graduating, Mr. Tomlinson went as a demonstrator and lecturer under the late Prof. Grylls Adams at King's College, London. His work enabled him to devote much time to research, which he followed most assiduously until about 1890. The subjects that specially attracted him were the various properties of matter, and a reference to the *Proceedings of the Royal Society* shows that in 1886, for example, he investigated the viscosity of air, the internal friction of metals and the effects of temperature and magnetism on this friction, and the velocities of sound in wires. Such subjects formed the matter of many extensive papers in the Royal Society's *Transactions*, and for this work he was elected a fellow on June 6, 1889. Among the others elected at the same meeting were: John Aitken, Horace T. Brown, Latimer Clark, Prof. McKenny Hughes, and Prof. Sollas.

In 1894, Mr. Tomlinson gave up the work at King's College for the post of principal of the newly built South-Western Polytechnic at Chelsea, and this work in technical education absorbed his activity until 1904. Among the many classes that he instituted was a Saturday morning class for team work in research. He and a number of the more advanced students met for the purpose of a united attack on some problem in elasticity or magnetism. The results were difficult to utilise, for although an experienced research worker himself, his assistants could claim but little facility at practical work.

In 1904, Mr. Tomlinson gave up the principalship and retired to Bexhill, where he devoted much time to wireless telegraphy, then in its infancy. It was characteristic of him that when he left London he told the present writer that he would never revisit it; and so far as the writer knows, he kept his word. Unfortunate circumstances deprived him of his small fortune, and as he was ineligible for any educational pension, he received a Civil List pension for his scientific work. During the War he served for a time as a science teacher at Lancing College.

Mr. Tomlinson was a man of intense devotion to a task that interested him, but he had also the capacity of putting aside a subject and taking up another with equal intensity. He was a most pleasant and cordial principal and received the devotion of his staff and students. The late Prof. Reinold was one of his most intimate friends, but he was not known to many of the younger school of physicists. His work was of importance in tracing the changes in properties of matter under varying conditions, and he brought to general notice many of these properties, which at his time were little appreciated. S. S.

DR. KARL BĚLAŘ.

WE regret to announce that Dr. Karl Bělař, of the Kaiser Wilhelm Institut für Biologie, Berlin, was killed in a motoring accident near Victorville, California, on May 24. He was returning with friends from a collecting trip in the Mohave Desert. Dr. Bělař's death at the age of thirty-six years is a tragic loss to the science of cytology. He combined a zeal for experiment and observation with a quite remarkable gift for the artistic expression of their results. After he left his native country, Austria, he was chiefly occupied with studies on animal cytology at the Kaiser Wilhelm Institut and at the Zoological Station at Naples. He was privat-dozent in zoology at the University of Berlin and a secretary of the Genetical Congress held there in 1927. In 1928 he was invited to the John Innes Horticultural Institution, where he spent two months that were highly profitable to all with whom he came into contact. In 1929 he was invited to visit the newly equipped California Institute of Technology, where he has since collaborated with the Morgan school of geneticists. He was about to return to Europe at the time of his death.

Bělař will be chiefly remembered for his masterly review of the behaviour of the nucleus in the Protista, and for his text-book of genetical cytology. In both these works, by critical analysis of discordant observations, he went a long way in reducing confusion to order. He contributed the article on Protozoa to the present edition of the "Encyclopædia Britannica". He will also be remembered for his remarkable ability in handling living and fixed cells. His technique (and his untiring industry) enabled him to show most satisfactorily the relation between what we see in permanent preparations and what is present in the living cell.

Bělař's friends in Great Britain and abroad will not easily forget the zest he put into his studies and the charm with which he instructed those less skilful than himself. C. D. D.

MISS ANNE L. MASSY.

ON April 16, after a few days' illness, Miss Anne L. Massy died at Howth, Co. Dublin. Living in her earlier years in the neighbourhood of that classical collecting ground of the old conchologists, the Velvet strand near Malahide, she soon acquired a very thorough knowledge, for an amateur, of the Irish marine mollusca, and when, in 1901, she was employed by the Irish Fishery Department in connexion with its biological work under the late E. W. L. Holt, her field of research was widened and she rapidly put herself in touch with the most recent systematic work on the Mollusca, taking a special interest in the pteropods and cephalopods.

With great industry and with that unconscious appreciation of differences and resemblances indispensable to a systematic worker, Miss Massy worked steadily through the Irish fishery collections and published from time to time papers containing sound original work on Atlantic pteropods, deep-water and pelagic cephalopods, brachiopods, holothurians, and other groups. Later, as a more independent worker, she published several papers on collections from other parts, amongst which may be mentioned the *Terra Nova* Reports on Cephalopoda and Pteropoda; a very useful paper on the Cephalopoda of the Indian Museum (1916), useful papers on South African Cephalopoda, and an account, in collaboration with Mr. G. C. Robson, of the remarkable sexual dimorphism in *Doratosepion*.

Apart from marine studies, Miss Massy was keenly interested in birds, and for many years acted as honorary secretary to the Irish Bird Protection Society. Her death, unexpected and all too soon, takes away a careful, critical, and efficient though retiring zoologist with no ambition but to do her work thoroughly, and a valued friend to all who knew her.

WE regret to announce the following deaths:

Prof. S. W. Beyer, dean of the industrial science division of Iowa State College, known for his work in economic geology, on June 2, aged sixty-six years.

Prof. F. Wigglesworth Clarke, formerly chief chemist of the United States Geological Survey, honorary member of the Chemical Society and foreign member of the Geological Society, on May 23, aged eighty-four years.

News and Views.

IN his presidential address to the British Association at Oxford in 1926, and on many other occasions, the Prince of Wales has shown that he is fully aware of the part that scientific research and invention can play in promoting the welfare of the human race. He returned to the subject in the course of his presidential address to the Congress of the Universities of the Empire, delivered in Guildhall on July 3. "It is borne in upon us daily more clearly", he said, "that the material progress of mankind will depend in an ever-increasing degree on the application of modern science to modern industry". In our leading article this week (p. 45), we have dealt with the chemical industry of Great Britain, and it is shown that while it is suffering from the present world-wide economic depression, yet it has suffered less than other industries. It owes its position to the technical progress which has been made, and to appreciation of scientific methods in research, management, and salesmanship. Here is an immediate justification of the Prince of Wales's remarks, if such be needed. By his wide travels within and beyond the British Empire, the Prince has had unrivalled opportunities of acquiring broad views of men and affairs. This gives added weight to his words, which will, we hope, help towards a fuller recognition of the value of the scientific worker to the community. At the same time, the scientific worker must himself be prepared to take his share of civic responsibility, as indeed in most cases he is fully competent to do.

Two American aviators, Messrs. Post and Gatty, landed in New York on the night of July 1, having flown round the earth on a 'small circle' course in the northern hemisphere, in nine days. The approximate length of the flight was 16,000 miles, the longest single day's 'hop' being 2500 miles from Khabarovsk to Solomon, Alaska, crossing the Bering Strait. The machine used was an American-built Lockheed "Vega" specially prepared for fast long-distance flying. This has been hailed by the press generally as a flight round the world—a misnomer, in that a passage round the globe on a 'great circle' course would have needed a flight of approximately 24,000 miles. As a feat of physical endurance on the part of the crew this performance is probably unsurpassed, but it was carried out on a special machine and in such a manner that it does not prove that such flights are yet commercially possible, or that the repetition of such risks is even advisable. It is, however, a tribute to the steady technical improvement in aeroplane and aero engine design. The only previous occasion of a similar flight was in 1924, when it was attempted by four U.S. Army aeroplanes. Only two completed the journey, after considerable delay due to the necessity for many repairs and the substitution of several new engines *en route*.

ACCORDING to a dispatch from the Paris correspondent of the *Times* in the issue of June 29, the Public Prosecutor of Cusset has reported in favour of dropping the prosecution for fraud against M. Émile Fradin, who was responsible for the discovery of inscribed clay tablets and other alleged antiquities at Glozel. The Public Prosecutor finds that there is no evidence to show that M. Fradin was responsible for placing these objects in the ground, and further that, as he did not profit, it would not be possible to maintain an action for fraud, as it must be shown that the deceit was practised for profit. The report, which must of course be accepted as in accordance with the principles of French law, is, to say the least, unfortunate from the point of view of the archæologist, if, as it suggests, it means that anyone is at liberty to foist an impudent imposture on an unsuspecting public, provided care is exercised to avoid the appearance of direct financial gain. It must be obvious that many advantages might, and indeed did, accrue to the Fradins and those associated with them, even if up to the time the bubble burst they had not actually exploited financially any of their 'precious' finds.

CITRUS growing in Southern Rhodesia is yet in the early stages; the total export for the year 1930 was 170,000 cases, 91 per cent of which was grown on the British South Africa Company's estates. The directors of this Company, which owns more than one half of the present plantings in this Colony, have adopted the policy of basing the industry on scientific research. With this object in view, they have increased the research staff in Southern Rhodesia, and on April 1 created a citrus experimental station of their own, with headquarters on the Mazoe Citrus Estate. The director of this station is Dr. W. J. Hall, assisted by a staff consisting of a chemist, plant pathologist, entomologist, and research horticulturist. Adequate laboratories are nearing completion, and will be suitably equipped, and a large plot of land has been allotted for use as an experimental plot for all field experiments. The prime function of the station is research, and all work undertaken will be in accordance with the practical needs of the citrus industry in Southern Rhodesia. Some of the major lines of investigation will be to establish those varieties most suitable to local conditions; improvement of strains by continuous and intensive bud selection; investigation of stock and scion relationships; the entire manurial programme; breakdown and wastage in transit; study of plant diseases and insect pests with the view of devising control measures and reducing the losses from their causes to a minimum. It is hoped to print an annual report, and also to publish from time to time such results as may appear worthy of record.

DELESSERT, in his work "Voyages dans les Deux Océans", published in 1848, says on p. 94, when referring to parrots in Australia, that the budgerigar (*Melopsittacus undulatus*) is the rarest and most charming, and that it is most amusing to hear it speak, which it can easily be taught to do. Gould, eight years before, had taken to England what he believed were the first living specimens to be imported: abundant importations soon followed, but the bird has turned out to be so readily bred in captivity that for a good many years now, until the recent ban on the importation of parrots, owing to the fear of psittacosis, the market was chiefly supplied by French-bred specimens, which were finer than the Australian-caught birds. Yellow varieties have been recorded among the wild Australian stock, and this variation has long been fixed among the tame birds. A blue form had been heard of here, but passed almost into a legend among aviarists, having originated in Belgium so long ago as 1880. In 1910, it was exhibited in London, and aroused very keen interest, which was renewed by further introductions after the War. Blues were eagerly sought for and bred, either pure or crossed with greens, which dominated this colour as well as yellow. Cross-bred budgerigars, on the whole, conform to Mendelian expectation, but the main interest of the impetus given by the new colour and the ban on parrot importation is that the birds are now often taken when young and taught to talk, showing, according to accounts which have recently appeared in *Cage Birds*, as much proficiency as an average grey parrot. A thoroughly domesticated creature which can be taught to speak should be of interest to any laboratory of eugenics, and the budgerigar is as clean and frugal as it is attractive, so that it is ideal for experimental breeding.

THE Committee on Organisation of the Sixteenth International Geological Congress has decided to postpone the meeting of the Congress for a year, to the latter part of June 1933. It was felt that the generally adverse economic conditions throughout the world made this postponement desirable. The following topics for discussion have been tentatively adopted: Measurement of geological time by any method; batholiths and related intrusives; zonal relations of metalliferous deposits; major division of the Palæozoic system; geomorphogenic processes in arid regions and their resulting forms and products; fossil man and contemporary faunas; orogenesis. The routes of the excursions have been selected and work is well advanced on the preparation of the guide-books. A series of excursions before the Congress of from five to twelve days in length will cover the eastern and central States. These will, so far as is possible, be arranged to appeal to specialists in various branches of geology. There will also be a number of short excursions in the vicinity of New York. During the session of the Congress, which will last about a week, several short trips will be made to points of interest in the vicinity of Washington. The excursions after the Congress will include two in the north-central States—one for glaciologists in Illinois, Iowa, and Wisconsin, and the other for mining geologists in the Lake Superior iron and copper districts, each of about ten days duration—and two transcontinental trips, each of about thirty-five days. Further particulars can be obtained from the Secretary, Sixteenth International Geological Congress, U.S. Geological Survey, Washington, D.C.

"CRIMINAL STATISTICS", being the statistics relating to crime, criminal proceedings, and coroners' investigations for the year 1929 (London: H.M. Stationery Office, 1931. 3*s*. 6*d*. net) raises some interesting problems. It is impossible to follow up all the questions suggested, but one that must be of importance to everyone is the significant relation between crime and industrial depression. The report states that even in normal times there are certain differences between the incidence of crime in industrial areas and non-industrial areas. In 1921 the incidence of crimes against property and of sexual offences was higher in the north of England than in the south, although in crimes of violence against the person it was slightly lower. In 1929 the position in the north had become relatively worse; although the population had increased only by 4 per cent, while that of the south had increased by 5 per cent, yet the increase in the incidence of all classes of indictable offences was 34 per cent as against 24 per cent in the south. The report suggests that the reason is the state of industrial depression from which the north of England is suffering. Analysis of the ages of the offenders shows that the incidence of crime among men above thirty years of age has not increased, but that as regards boys under sixteen years of age, the number found guilty in the north of offences of dishonesty is much higher than in the south. Industrial depression introduces conditions particularly detrimental to the young in destroying the direct incentive of good prospects, quite apart from the bad effects of idleness or inadequate work. The hope is expressed in the report that, when trade and industry improve, this kind of crime will diminish.

IN the last number of the *Archives de l'Institut de Paléontologie Humaine*, Prof. Charles Fraipont, of Liège, has published a memoir on the "Cerebral Evolution of the Primates, with special reference to the Hominidæ", which he dedicates to the distinguished editor, Prof. Boule, whose anthropological views he, for the most part, adopts. Although references are made to the works of Dubois and Tilney, the author seems to be unacquainted with the significant researches on the distinctive attributes of the human brain and their biological significance which have been accomplished in Great Britain, the United States, Germany, Austria, and other countries, besides those in France and Belgium, during the last thirty years. If Prof. Fraipont had made himself acquainted with these works he would scarcely have made such surprising claims as he puts forward in this memoir. Among other bizarre arguments, he states that the refinement of the hand made possible the reduction of the muscles and bony parts of the face, and that the latter changes permitted the hypertrophy of the frontal lobes of the brain, and consequently the emergence of human intelligence. There are some excellent photographs and radiograms of the bones of the leg to illustrate the evolution of the lower limb in apes and men.

M. FERDINAND LOT in his Sir John Rhys Memorial Lecture for 1930 on "Bretons et Anglais aux V^{e} et VI^{e} siècles", which has recently been issued by the British Academy (London: Oxford University Press,

1931. 1*s*. 6*d*. net), refers to the sources of information on this period in terms which fully justify our recent comments in these columns on the suggestion put forward by the editor of *Antiquity* that a chair for the study of English archæology is badly needed. He points out that, with the exception of Gildas, there is no literary authority of weight for the invasion and early years of domination of the Saxons in England; and that study of archæological remains and their distribution alone, within certain limitations, will afford any basis for our knowledge of the relation of Saxon and Briton in this and the succeeding period. Yet, as M. Lot points out, the fact that the Saxons found a place of refuge in England where they were able to develop an independent political and economic life of their own undisturbed, while other migrant peoples on the Continent were unable to find any settled resting-place, constitutes the Saxon invasion of Britain as one of the most important events in the history of the world. This, which a moment's reflection will show is no exaggeration, makes it all the more remarkable that so little provision should be made for systematic study of the earlier stages of Anglo-Saxon and English culture.

FROM the fourth annual report of the Australian Council for Scientific and Industrial Research it is evident that important results of economic value have already been obtained, and that the necessity for further development along scientific lines, if prosperous conditions in the Commonwealth are to be restored, is fully recognised. Through the discovery of methods for controlling plant disease, notably in the cases of bitter-pit in apples and bunchy top in bananas, large savings have already been made. The eradication of weed pests such as St. John's wort and prickly pear, by means of the introduction of insects which feed upon these plants, continues to prove amazingly successful, the monetary value of this line of work amounting to millions of pounds. The outstanding achievement in connexion with animal research is the discovery of an effective vaccine against black-disease of sheep, and animal nutrition investigations, though but recently begun, are already yielding valuable results. Since the establishment of the Council's Viticultural Research Station at Merbein the yield of dried fruit per acre has been doubled and the quality considerably improved. Marked success has also attended the division of forest products research, satisfactory paper pulp being obtained from hardwoods previously regarded as entirely unsuitable for this purpose. Many other fundamentally important lines of research are being carried out, and, to quote from the report, " it is obvious that, despite its comparatively recent formation, the Council has already been responsible for large national savings many times greater than its annual cost, and that its possibilities in the not far distant future are even greater."

METEOROLOGISTS have not yet succeeded in giving a clear account of the general circulation of the earth's atmosphere, that is to say, of the distribution of the prevailing winds at various seasons. It is true that the main features of the surface circulation are known, and that attempts have been made to show the circulation at greater heights by deductions based on surface pressure and temperature and the known relationships between horizontal pressure gradient and wind. Such theoretical representations cannot be accepted indefinitely as a substitute for accounts based on actual observation. On land, owing partly to the stimulus received from the needs of aviation during the War, the gaps in our knowledge are gradually being filled by organised exploration with the aid of pilot balloons. One is glad to learn from an article by Commdr. L. G. Garbett, superintendent of the Royal Naval Meteorological Services, in a recent issue of the *Marine Observer* (No. 91), that our very scanty knowledge of upper winds over the oceans is being rapidly increased by systematic observations undertaken on a number of His Majesty's ships, according to a scheme initiated in 1925. During 1931 no fewer than 1500 observations are to be made in various parts of the world, and this year's programme is to be repeated during forthcoming years. The observations are being received at the Meteorological Office, Air Ministry, and are to be shown graphically on a network of 'squares' measuring 10° in latitude and longitude. The soundings frequently extend up to a height of 20,000 feet when clouds do not interfere, and one made in Australian waters reached 49,000 feet, that is to say, nearly the same level as that to which Prof. Piccard ascended recently. In some instances, measurements of temperature are made. The accumulated material will be available at the Air Ministry for consultation by aviators and for meteorological research.

ONE of the great advantages of an electrical supply is the ease with which it can be applied to provide labour-saving devices. The switches for electric fires are now frequently fixed so that without moving the armchair it is possible to turn it on, regulate the heat it gives out, and turn it off. There is no domestic drudgery involved. At first sight some of these labour-saving devices seem almost unnecessary. For example, when measuring the insulation resistance of a network a voltmeter reading has to be divided by an ammeter reading. The arithmetic involved is very simple, but there is a device in much demand which by placing the pointers of the instruments on opposite sides of the same dial tells the resistance by noticing their point of intersection and seeing the curve on which it lies. Similarly, on the dashboard of electric motor-cars the ammeter and voltmeter pointers by their point of intersection indicate the horse power expended on the car. Ingenious experimenters have recently invented devices for shutting and opening windows by pressing buttons, and devices for regulating and controlling their radio-receiving sets from a distance are coming into use in America. Many devices with this end in view are described in the *Wireless World* for June 17. It is well known that most set owners only listen in to a few stations. One device consists of a small metal box on the top of which is a set of six buttons. Two more buttons turn the receiver on or off, and a slight pressure on two other buttons varies the volume of the sound. A tiny lamp lights when the set is in operation, and indicates by its varying brilliancy whether a station is tuned in to its most sensitive point on the dial. In elaborate installations in large mansions a more complex dialling system is used. In Great Britain the commonest arrangement is a switch which allows the user to turn off his set the last thing at night without getting out of bed.

THE *Transactions* of the Institute of Marine Engineers are issued in monthly parts, and these include many articles from the technical press which are of interest and value to the members, who, owing to the nature of their calling, can seldom visit libraries. The inclusion of these notes has caused the volumes to become rather bulky, and so with the commencement of vol. 43 the size of the pages has been doubled. It is now 11 in. by 8½ in. and corresponds with the size of the *Transactions* of the Institution of Naval Architects. The alteration is a great improvement and will be appreciated by all who read the *Transactions*. Of the two monthly parts issued in the new form and size, that for February contains the paper on the "Electrical Equipment of a Modern Ship" read by Mr. J. E. Allan on Jan. 13, while that for March contains the paper on "Water Tube and/or Scotch Boilers" read by Mr. H. E. Yarrow and S. Hunter, jun., on Feb. 10. Both papers are accompanied by a full report of the discussions. The February issue also contains a portrait of the late Sir Charles Parsons, who was a past president of the Institute. The Institute took a foremost part in arranging the memorial service held on Mar. 22 in St. Botolph's, Aldgate, to commemorate the centenary of the death of William Symington, the father of marine engineering, whose death took place in a house in Burr Street not far from the spot now occupied by the headquarters of the Institute.

THE Engineering Experiment Station of the University of Illinois includes a locomotive laboratory in which tests of service locomotives can be made. Such a laboratory is urgently needed in Great Britain and has, for some time past, been under the consideration of a committee appointed by the Department of Scientific and Industrial Research and presided over by Sir Alfred Ewing. The laboratory at Urbana, Illinois, was described in *Bulletin* No. 82, of the University of Illinois Engineering Experiment Station, while a recently issued *Bulletin*, No. 220, describes the tests of a Mikado-type locomotive equipped with Nicholson thermic syphons, conducted in co-operation with the Illinois Central Railway Company and the Locomotive Firebox Company. A syphon is a supplementary water leg or circulating chamber riveted to the roof of the firebox and the bottom of the tube plate to stimulate the circulation of the boiler water and increase the transfer of heat. The results of the tests showed that the syphon-equipped locomotive possessed a definite and notable superiority over the non-syphon engine as regards both evaporation per pound of coal and boiler efficiency. Under identical conditions of operation, the weight of steam generated per pound of coal would be on the average 8·5 per cent greater with the syphons than without them. There are at the present time about 13,000 syphons in service on American and Canadian locomotives. Copies of *Bulletin* No. 220 can be obtained from the Engineering Experiment Station without charge.

A GREAT collecting expedition to Australia is announced by Science Service, of Washington, D.C. Harvard Museum of Comparative Zoology is determined that its collection of Australia's rare and strange animals shall be one of the largest and best-balanced collections in the world. To that end an expedition, led by Prof. W. M. Wheeler and having the advantage of the presence of Dr. Glover M. Allen, is to leave New York on July 25. The expedition is to be in the field for a year, and is to visit many isolated and little-explored faunal areas in Australia and Tasmania. In addition to mammals, birds, reptiles, insects, and other forms of animal life will be collected. We wonder how long the rare animals of the world will survive the tax of scientific collecting expeditions, and when the museum scientific worker will act on the principle that more is to be learned by studying creatures alive in their native haunts than by measuring their skins in a laboratory. We trust, in any case, that Australia will see to it that the 'bag' of the really rare creatures is strictly limited; for a bird in the bush, in such a case, is worth two in the hand.

IN continuation of its work for the good of mankind, the Institut International de Co-opération intellectuelle, Paris, has published an account of the organisation and activities of "Instituts Nationaux à l'Étranger". The brochure, of 124 pages, includes the names of two categories of institutions: research institutes established by any country in a foreign land, and institutes established in foreign lands to spread there a knowledge of the language and civilisation of the founder country. The objects of the institutes, their personnel, mode of subvention, date of origin, and publications are summarised—a first attempt to give a comprehensive survey of those scientific foundations in foreign lands, which not only make their contributions to scientific knowledge, but also, since they form centres of international scientific collaboration, add to the comity of the nations. Of the 87 research institutes, founded by 16 different countries in 25 other lands, Great Britain claims only 8, a poor figure compared with the 12 representing the United States, 17 representing Germany, and 24 representing France.

AN exhibition of the finds of Mr. Guy Brunton's expedition to middle Egypt during the past season opened in the Nimrud Gallery of the British Museum on July 2. A large number of objects from the earliest pre-dynastic periods, and from the sixth to twelfth, the nineteenth to twenty-sixth dynasties, and the Christian Coptic period of about A.D. 300–500 are shown. The 'Tasian' and 'Badarian' objects include a fine well-preserved black ripple bowl. An 'Amratian' bowl of red-painted ware has a crocodile and a number of small hippopotami moulded on the rim. Other Amratian objects include a number of anthropomorphic amulets of ivory and slate palettes of various forms, including birds and fishes. There is a large number of beads of various periods. The Coptic objects include a number of shoes, some of which had belonged to children.

THE New International Association for Testing Materials (N.I.A.T.M.), which was formed as a result of meetings in Amsterdam in September 1927, will hold its first congress in Zurich next September. The president is Prof. A. Mesnager. The work of the congress will be divided among four groups, namely, (a) metals, chairman, Dr. W. Rosenhain, of the National Physical Laboratory; (b) non-metallic inorganic materials, chairman, Prof. M. Roš, of Zurich; (c) organic materials, chairman, Prof. J. O. Roos, of Stockholm; and (d) questions of general importance, chairman, Prof. W. von Mollendorf, of the Staatliches Materialprüfungsamt, Germany. The proceedings will commence on Sunday evening, Sept. 6, with a reception in the Zurich Polytechnic and addresses by the president and others. The sections will meet each day in the Polytechnic, the plenary session taking place on Friday afternoon, Sept. 11. Visits to works, excursions to places of interest, and various entertainments are being arranged. Particulars of the travelling arrangements and hotel accommodation can be obtained by members affiliated to the British branch of the N.I.A.T.M. from Mr. G. C. Lloyd, 28 Victoria Street, London, S.W.1. The autumn meeting of the Institute of Metals will also take place in Zurich in the week commencing Sunday, Sept. 13—that is, immediately following the Congress of the N.I.A.T.M.

THE tenth annual conference of the Institut International de Bibliographie will be held on Aug. 25–29 at the Hague. In addition to the presidential address, by Prof. A. F. C. Pollard, and the reports of the secretaries, more than a score of papers will be presented. Although the activities of the Institut embrace all branches of knowledge, scientific and technological interests are very well represented, as is shown by the following selection from the papers: "Le rôle et l'Organisation de la Documentation de la *Revue Générale de l'Électricité*", by E. Beinet; "Probleme der bibliographischen Praxis", by Dr. Julius Hanauer, of the A.E.G.; "L'Organisation de la Documentation dentaire par la F.D.I.", by Dr. Émile Huet, delegate of the International Dental Federation; "Rapport sur le 'Repertorium Technicum'", by J. M. C. Muller, Bataafsche Petroleum Company; "International Abstracting and Indexing of Scientific and Technical Literature", by Sir Frederic Nathan; "Aufgaben und Organisation eines Referatenorgans", by Dr. Maximilian Pflücke, of the *Chemisches Zentralblatt*; "The Bibliography of Physiology and the Application thereto of the Decimal Classification", by Dr. J. G. Priestley (Oxford); "La Classification décimale dans le Domaine de la Médecine", by Dr. René Sand, Ligue des Soc. de la Croix Rouge. In addition to the more serious business of the Conference, a very interesting programme of receptions and visits has been arranged. Full particulars may be obtained from the Secretariat, Institut International de Bibliographie, Carel van Bylandtlaan 30, La Haye, Netherlands; or from the honorary secretary, British Society for International Bibliography, Science Library, South Kensington, S.W.7.

THE following have been elected foreign members of the Royal Society: Prof. Charles Fabry, of Paris, distinguished for his work in connexion with the modern interference methods in spectroscopy and the modern system of wave-length standards; Dr. Emmanual de Margerie, of Strasbourg, distinguished for his work on the tectonic geology of parts of France and especially of the Pyrenees; and Prof. Heinrich Wieland, of Munich, distinguished for his work on organic chemistry.

THE Right Hon. Sir Herbert Samuel, M.P., has accepted the presidency of the British Institute of Philosophy in succession to the late Lord Balfour. Distinguished lecturers during the forthcoming session will include: Sir James Jeans, Prof. S. Alexander, the Dean of St. Paul's, the Archbishop of Armagh, Prof. J. S. Haldane, and Dr. C. D. Broad.

WE regret that a misprint has appeared in the letter entitled "Ultra-Violet Absorption and Raman Effect for Hydrazine" by S. Imanishi in NATURE of May 23, p. 782. The line 1120 is attributed to the N-N (single bond) vibration in the hydrazine molecule and not to the N-H vibration as stated in line 34 of the communication.

IT is stated in a *Bulletin* of Science Service that Dr. L. O. Howard, formerly chief entomologist of the United States Department of Agriculture, will receive the Capper award for 1931. This award consists of a gold medal and a cash purse of five thousand dollars. It was founded by Senator Arthur Capper of Kansas, and is given each year to a scientific worker who has made notable contributions to the progress of agriculture.

AN addition must be made to the list of zoological journals, with the appearance in December 1930 of the first part of volume 1 of the *Journal of Science of the Hiroshima University*, Series B, Div. 1 (Zoology). The first portion contains three papers by Yoshio Abe; two of these deal with mammals, and to them further reference will be made in our "Research Items". The journal is beautifully printed, both as regards text and plates, and it is announced that reports are to be published as they are received, and that each volume is to contain about 200 pages. Two of the papers in the first part are in German and one is in English.

THE issue of the *Quarterly Journal of Microscopical Science* for April contains an article of eighteen pages by Prof. E. S. Goodrich on the work of the late Sir Ray Lankester, which gives an excellent review of the chief points in the long series of his published works. Lankester's first papers, on Gregarines and on Tubifex, appeared in 1863, and his subsequent publications ranged over almost all the principal classes of the animal kingdom. The article brings out clearly the great part Lankester played in the progress of zoological science, and incidentally indicates how many of the terms employed in modern zoology and embryology are due to him.

The first three numbers of a new publication which abstracts the current papers on plant genetics (with the exception of herbage crops) have now appeared. They are published from the Imperial Bureau of Plant Genetics (School of Agriculture, Cambridge) and are issued quarterly at a price of 5*s.* per annum, or 1*s.* 6*d.* for single copies. The three numbers contain respectively 23, 36, and 52 pages, and will be of much service to all workers in plant genetics. In the abstracts, particular attention is given to practical developments in plant breeding and to the genetics of economic plants, but papers of general or theoretic interest are included.

The Faculty of Medicine of the Egyptian University, Cairo, has published a volume of 506 pages entitled "The Bibliography of Schistosomiasis (Bilharziasis), Zoological, Clinical, and Prophylactic". It has been compiled by Mohamed Bey Khalil, professor of parasitology in the University, and is divided into an alphabetical index of authors (232 pages) and a classified index of subjects. The Schistosomes constitute a family of the Trematoda or flukes, of which three species attack man and others are met with in other animals. The history of schistosomiasis commenced with the discovery of *Distomum hæmatobium* as the cause of endemic hæmaturia (urinary hæmorrhage) in Egypt by Theodor Bilharz in 1851, a half-tone plate of whom forms a frontispiece to the volume. The bibliography is a monumental piece of work, creditable alike to the author, the University authorities, and the printers, Paul Barbey of Cairo.

The Ministry of Health has issued an eighth memorandum on cancer (*Circular* 1186). It deals with cancer of the lip, tongue, and skin, and an analysis of the recorded deaths by sexes shows that lip and tongue cancers are much more frequent in the male sex, but skin cancers are only slightly more prevalent among males if certain 'occupational' cancers (due to soot, tar, oils, etc.) be excluded. The curability and survival rate for lip and skin cancers are high, but for the tongue the results of treatment are much less favourable. With lip and tongue cancers, some irritative condition is a common antecedent, and syphilitic lesions of the tongue appear to predispose to cancer of this organ. There is nothing to incriminate ordinary tobacco smoking as a predisposing cause of cancer, provided the mouth and tongue are in a healthy condition. In the skin, warts, birthmarks, and scars are liable to develop cancer, but particular sources of irritation over a long period are the predominant cause of cancer, such as X-rays, tar and pitch, soot, certain mineral oils, arsenic, possibly heat rays, etc.

We have received from Messrs. Baird and Tatlo [illegible] (London), Ltd., a copy of a book entitled "Anal [illegible] Reagents, Standards and Tests", which [illegible] recently issued in conjunction with Mess [illegible] and Williams. The book [illegible] common reagents, in each [illegible] tion. The use of the book will enable the chemist to check for himself the purity of the materials he purchases, and should prove very useful in analytical laboratories. Several organic compounds are included.

Messrs. Henry Sotheran, Ltd., 43 Piccadilly, W.1, have sent us part 1 of their "Catalogue of Exact and Applied Science" dealing with periodical publications, general and collected works, and mathematics. Nearly 2000 works are included and (as is usual with Messrs. Sotheran's catalogues) many valuable bibliographic notes are appended. The catalogue is one that should not be missed. Two further parts are promised dealing with astronomy, physics, geology and meteorology, chemistry and chemical technology, and engineering.

Applications are invited for the following appointments, on or before the dates mentioned:—A junior laboratory and lecture assistant in the physics department of the University of Manchester—Prof. W. L. Bragg, University, Manchester (July 14). An assistant under the Ministry of Transport (Roads Department) for work in connexion with road traffic —The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (July 14). A probationary tutor in economics and allied subjects at University College, Nottingham, for extra-mural classes—The Registrar, University College, Nottingham (July 15). A lecturer in the Department of Chemical Engineering of University College, London—The Secretary, University College, London, Gower Street, W.C.1 (July 17). A chief librarian and clerk to the Library Committee of the County Borough of Ipswich—The Clerk to the Library Committee, Central Public Library, Ipswich (July 18). An assistant lecturer in mathematics in the University of Manchester—The Registrar, University, Manchester (July 20). An assistant superintendent of classes for instruction in the principles of boot and shoe manufacture, under the Northamptonshire County Council Education Committee—The Secretary for Education, County Education Offices, Northampton (July 20). A temporary assistant lecturer and demonstrator in botany at the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (July 23). A tutor of psychology and philosophy at Loughborough College—The Registrar, Loughborough College, Leicestershire (July 25). A temporary technical assistant under the Directorate of Ordnance Factories of the War Office—The Permanent Under-S [illegible] of State for War (C.4), War Office, Whit [illegible] ig. 1). *A head of the Depart-* m [illegible] nd Rubber Technology of the [illegible] —The Clerk, Northern Poly- [illegible] A woman senior assistant [illegible] information bureau of the [illegible] Flour Millers—The [illegible] ciation of British [illegible] Albans. Two [illegible] of Ballistic [illegible] ich—

Influence of Hydrogen on Chemical Changes in Silica Vessels.

CHEMICAL literature has of late contained several references to the influence of adsorbed hydrogen on silica on chemical changes taking place in silica vessels. At the same time the fact that silica, at moderately high temperatures, takes up very large quantities of hydrogen is stressed, and it is assumed that this hydrogen is adsorbed, that is to say, exists as a film on the gas-glass interface. However, the following experiments seem to indicate that this is only a part of the story.

During the past year we have been studying the condensation of ethane at 600°, by heating the pure gas, generally at concentration of 0 025 gram molecules per litre, in sealed silica tubes for periods up to eight hours. During the first few minutes a part of the ethane is decomposed into ethylene and hydrogen; but when equilibrium conditions are approached this reaction slows down, so that the hydrogen content of the tube varies but little or not at all during the latter periods. Hydrogen plays no direct part in the secondary reaction, or reactions, which lead to the formation of methane and a condensate of aromatic compounds.

Now, though hydrogen plays no direct part in the secondary processes, it plays a very important indirect part; for if hydrogen is added to the ethane to increase the hydrogen content of the reaction mixture by a small amount, the rate of formation of condensate diminishes rapidly, and a relatively small increase in the hydrogen condensate inhibits the formation of condensate altogether. However, we will only refer to this point in passing.

Down to a few weeks ago we had carried out a large number of experiments, using about twenty different silica reaction tubes, and had come only to the conclusion that the hydrogen played some part in the reactions, which we were absolutely unable to understand or to control. We were unable to reproduce experimental results, though in two series of experiments an apparent regularity nearly misled us to the conclusion that the condensation of ethane was primarily a *unimolecular* process.

Reasons which we cannot set forth in detail led us, however, to adopt a method of experiment which gave results which we believe to be both new and interesting. We observed that the results were more erratic when we used thin silica tubing than when moderately thick walled tubing was used, suggesting that, since hydrogen can pass fairly rapidly through silica at 600°, the solubility of th [illegible] in the silica was a factor which must b [illegible] since the hydrogen in the adsorbed la [illegible] be in equilibrium with the hydro [illegible] d gaseous phases. We therefor [illegible] of experiments. In one, we [illegible] reaction tube, and heat [illegible] hydrogen to the reac [illegible] ing, cooling, and [illegible] The other was a [illegible] an outer tu [illegible] filled [illegible]

We suggest that the idea which led us to carry out these experiments is a correct one, and that in dealing with such materials as silica and palladium, through which hydrogen passes readily, the equilibrium system is rather a complex one, and consists of:

Glassy phase :: Glass-gas interface :: Gas-glass interface :: Gas phase

It is possible that in the solid or glassy phase the hydrogen may be more highly dissociated than in the gaseous phase, so that we have to consider the equilibria:

Glassy phase :: Glass-gas interface :: Gas-glass interface :: Gas phase

$$H_2 \rightleftharpoons 2H \quad \boxed{H_2 \rightleftharpoons 2H} \quad H_2 \rightleftharpoons 2H \quad \boxed{H_2 \rightleftharpoons H_2} \quad H_2 \quad \boxed{H_2 \rightleftharpoons H_2} \quad H_2$$

The hydrogen atoms in equilibrium in the gas-glass interface and in the gas phase may be so small as to be negligible; however, the life of hydrogen atoms passing out from the glass-gas interface into the gas-glass interface may be long enough to effect those processes which are commonly attributed to atomic hydrogen in the adsorbed layer (gas-glass) on the silica.

Now that we have been able to stabilise the silica-gas system, and to obtain reproducible results, we have been able to study another phenomenon, which is rather striking. The process of condensation of ethane with formation of methane and condensate appears to be catalysed and accelerated, so that, representing the amounts of product obtained as ordinates and time as abscissæ, the curve representing the change, in either case, has an upward tendency. Now over a range between 570° and 610° C., and at concentrations between 0·025 and 0·0125, and whether in the thick-walled tube or in the double-walled tube, the rate of formation of condensate or of methane undergoes so sudden a change after a period which is always almost exactly 2½ hours from the commencement of the experiment, that one is inclined to connect the phenomenon with some change of an *explosive* character such as all forms of silica undergo when changing from the α to the β form, or vice versa. What the nature of the change is we do not know, but we suggest that it may be a chemical change, facilitated by the fact that the silica surface, like the interior surface of all tubes, is in tension, when, as we now know, reactions can take place which general thermodynamic data would indicate to be impossible.

These matters are the subject of further investigations.

The Composition of the Blood of Aquatic Animals and its Bearings upon the Possible Conditions of Origin of the Vertebrates.

FORTY years ago a suggestion was made (Bunge)[1] that the sodium chloride in the human tissues might be a relic, an inherited feature of some aquatic marine ancestor. The same idea was expressed in certain papers by Quinton,[2] who stated that so far as salinity [illegible] concerned the blood of most animals is an altered [illegible] water. In 1903,[3] Macallum, then unaware of the [illegible] stions of Bunge and Quinton, advanced the [illegible] that the blood plasma of vertebrates and [illegible] tes with a closed circulatory system is, in [illegible] a reproduction of the sea water [illegible] riod in which the prototypic present-day ocean as due to changes in the composition of the sea water since palæozoic or mesozoic times. Macallum followed up his first statement by more detailed papers, and made some valuable analyses of blood to support his thesis. He is now generally credited with being the originator of this interesting conception. In 1912 I discussed the matter[4] from the point of view of certain experiments and observations on marine and fresh-water invertebrates, and came to the conclusion that whilst one might accept the well-regulated saline composition of the blood of teleost fishes, amphibia, and the higher groups as being to a certain extent an heirloom of an ocean environment, there was no reason whatever to believe that the favoured salinity associated with independence represented the composition of any particular primeval ocean. At that time I stated that the investigations of osmotic regulation did not preclude the idea that the early vertebrates with an independence in blood salinity had evolved in fresh water.

Recent researches have gone far to confirm this view. It is now fairly well known that the blood of marine invertebrates resembles very closely in saline contents the sea water in which they live, and the concentration and composition is very dependent upon this medium. It is, however, becoming clear that these conditions only hold good in the sea. Marine invertebrates which have invaded brackish and fresh waters often present an independence of the blood which is not at all unlike that of the vertebrates. For example, in both the fresh-water crayfish and a frog immersed in water, there is a constant and controlled diffusion inwards of water and a regulated output from the excretory organs. A new fresh-water crab (from a river of New South Wales) with which we have been experimenting retains a constancy of blood salinity which is less than half that of the ocean from which it has undoubtedly wandered, yet its sojourn in fresh water cannot have been of long duration. During recent years, oceanographers and geologists have been more inclined to be conservative with their conceptions of increase in the salinity of the ocean since mesozoic or palæozoic times, and palæontologists are well disposed to the origin of the early vertebrates in fresh or brackish water. It does not really matter, however, from the present point of view, whether the ocean has become more saline or not. Comparative and experimental physiology gives little support to the view that the regulated blood salinities of the vertebrates represent the salinity of the media in which their ancestors evolved that constancy.

We can only accept the universal saline composition of the blood of *metazoa*—with its variations—as a possible reflection of a long-continued existence and probable origin in a saline medium.

Effect of Light on Urediniospores of Black Stem Rust of Wheat, *Puccinia graminis tritici*.

AT the Dominion Rust Research Laboratory, Winnipeg, the effect of ultra-violet light on the development of the rust organism has been studied by me. As a result of certain experiments, evidence was obtained that the pigment in the epispore of a normal urediniospore protected it from injury by ultra-violet light. The experiments in which this evidence was obtained were carried out in the laboratory, and the source of light was a mercury vapour sun lamp. These experiments were concluded and others were commenced out of doors, the source of light then being the sun.

As these experiments progressed, an interesting phenomenon was observed. Urediniospores of black stem rust, when dusted lightly on the surface of distilled water and exposed either to direct sunlight or very strong diffuse light, did not germinate, whereas similar spores kept under the same conditions in the dark germinated very readily.

On bright days during April and May experiments of this nature have been carried out and spores have been exposed for varying periods, generally from 9 A.M. until 4 or 5 P.M. The results have always been the same—the spores have not germinated until the light intensity was low.

At first it was thought that the spores had been killed by the ultra-violet light emanating from the sun. When, however, the dishes containing the spores were covered by ordinary glass, and also by a glass transmitting the ultra-violet rays, the same phenomenon was observed.

Other experiments were carried out to see if this inability to germinate was due to existing temperature or humidity conditions. When, however, the spores in the dark and the spores in the sunlight were under approximately similar conditions with respect to temperature and humidity, those in the sunlight did not germinate.

In no case when urediniospores have been dusted on the surface of distilled water has germination been observed to take place in strong sunlight. In the dark these spores germinated readily, and germination was well advanced within two hours. Moreover, when spores exposed out of doors were taken into the laboratory they germinated in a normal manner. In controlled experiments in the laboratory dark room, using ten hundred-watt lamps, it was noted that germination was higher the farther the spores were placed from the source of light.

It seemed clear, therefore, that the reason these spores did not germinate was due in some way to visible white light and the intensity of it.

Standard Wratten light filters were then used, and the spores were covered by these and exposed to sunlight. It was observed that the spores germinated abundantly under the green and blue filters, but that only occasionally did any spores germinate under the red, scarlet, orange, yellow, or purple filters. When the light intensities were low, however, germination took place.

To confirm this observation a prism was used to split the sunlight into its component parts, which were allowed to fall on spores contained in ring chambers. No germination took place at the red end of the spectrum. To confirm this, spores were dusted lightly on to the surface of different dyes, and it was observed that they failed to germinate on Congo Red when exposed to sunlight; but on Light Green germination took place. In both cases, in darkness, on solutions of the same concentrations they germinated normally.

Pursuing these observations, other filters were tried, chiefly of different greens and blues. It was noted then that germination decreased when certain green and certain blue filters were used. The more yellow in the green and the more light blue in the green the more pronounced was the inhibition.

In addition to spores of different physiologic forms of *P. graminis tritici* this same phenomenon—that is, the inability to germinate in sunlight or under red, orange, yellow, and purple filters when exposed to strong sunlight—has been observed with different physiologic forms of *P. graminis avenæ* and, at the present time, other fungal spores are being investigated. If it may be assumed that the mycelia react in the same way as the spore and its germ tube to light of different wave-lengths, then these observations suggest some very interesting possibilities.

In a letter such as this it is not possible fully to outline the complete observations of these preliminary investigations; in consequence the results so far obtained with certain of these physiologic forms of rust and with other fungi, will be communicated elsewhere, and the work will be continued.

Dominion Rust Research Laboratory,
Winnipeg, Man., June 1.

Ultra-Violet Rays and Mosquito Larvæ.

RECENT work which I have been conducting at this laboratory on the possible effect ultra-violet rays may have on the activation of ovarian function in female mosquitoes, has disclosed the fact that mosquito larvæ are highly susceptible to a remarkable form of injury by radiations from the unshielded mercury-arc generated by the ordinary Cooper-Hewitt vacuum type of quartz lamp.

Larvæ in water contained in open watch-glasses when exposed to the rays at 12 inches from the lamp immediately exhibit an intense irritation. After an irradiation of 3 minutes' duration there is evidence of partial paralysis, in that the larvæ show signs of slight ventral curvature while resting at the water surface; otherwise, they are apparently normal in their responses and swimming movements. However, if such larvæ are kept under close observation, the rapid development of a progressive type of injury is made evident within a few hours. The paralysis increases, the ventral curvature becomes more and more pronounced, and usually by 6 hours after irradiation severe injury to the internal tissues is distinct. The injury takes the form of a progressive histolysis of the connective tissue, muscles, fat-body, etc., first along the dorsal region of the thorax and abdomen, then gradually extending to the underlying tissues, until ultimately the larvæ, bereft of a large mass of tissues, present an astonishing appearance. The chitinous integument is itself unaltered, and consequently extensive internal spaces are formed where tissue histolysis has taken place. These spaces, filled with the fluid product of histolysis, are perfectly transparent except for the ramifications of the tracheæ, and finally, the still living larvæ are reduced to a condition where only a comparatively narrow band of tissues remain along the ventral region of the body. The larvæ are then practically immobile, lying at the bottom of the water-container, but the action of the heart continues feebly for some length of time, even after the respiratory system has completely collapsed by paralysis of the constrictor-dilator nerve-muscle mechanism.

Under the rays of a lamp which has not operated for more than a total of 150 hours, the minimum duration of exposure necessary to produce fatal injury of this nature in the larvæ of both *Aëdes* (*Stegomyia*) *ægypti* L. and *Culex* (*Culex*) *pipiens* L. has been found to be a period of 45 seconds. The rate of the induction of these tissue changes is directly proportional to the duration of irradiation over fairly wide intervals, while the period occupied by the progress of the process, and before the ultimate death of the larvæ occurs, is inversely proportional to the duration of the irradiation.

Two distinct types of injury have been revealed. (1) A direct injury to the motor nervous system indicated by immediate partial paralysis of certain muscles, and the inhibition of the pulse-rate and tone of the heart. The heart is one of the first organs to suffer injury, but, strangely enough, is the last to be put entirely out of action. (2) An indirect injury leading to the progressive dissolution of many tissues, though principally affecting the fat-body.

The radiations responsible for these remarkable effects have been traced by the use of filters and subsequent spectrographic analysis to the band 2150-2850 A., the most effective radiations being apparently below 2500 A. A possible cause of the tissue histolysis and other injury would seem to be the disturbance of the normal electrostatic conditions within the living cell by absorption of the quanta of the lethal rays.

A full account of my investigations and the results of various experiments to determine the histological nature of the injury will be published in due course.

The Form of Fæcal Pellets and Specific Identification.

WHILE at Oslo, Norway, in 1927, I devised a bottom sampler capable of withdrawing a core of mud from the sea bottom, and at the same time preserving, as *in situ*, the surface layer. My object was to examine this upper layer of flocculent detritus with reference to its possibilities in providing potential food for bottom-living organisms. A description of this instrument with slight modifications was published by Moore in the *Jour. Marine Biol. Assoc.* (vol. 16, No. 2, pp. 589-594). When examining samples which I collected in the Clyde Estuary, I was struck by the characteristic form and sculpturing of fæcal pellets found in them, and, by keeping various members of the bottom fauna in captivity, was able to determine from which particular organism these fæcal pellets were derived.

Doubtless Mr. Moore[1] will remember my discussing the matter with him at Millport Marine Laboratory in 1929 before he commenced his investigations on marine muds.

I may mention here that a distinct stratification in the core extracted from the bottom was noticeable, and my examination showed that successive layers were characterised by fæcal pellets derived from different species, and in some cases different groups, of organisms. A history of the nature of the population in a specific area over a period was thus possible.

Not only were these layers characterised by the fæcal pellets of different organisms, but also they registered more or less faithfully the amount of land drainage in the particular neighbourhood.

I was therefore interested to read in Mr. Moore's letter that he has been so successful in his investigations, which in part confirm my observations. The detailed published results of his work should be valuable.

The Theoretical Magneton Numbers in Weiss Units.

As in several cases the experimental ionic magneton numbers may be regarded as established to within a few hundredths of a Weiss magneton, and as, on the other hand, the theoretical values given by Hund,[1] Laporte-Sommerfeld,[2] and Bose-Stoner[3] are accurate only to a few tenths of a magneton, it may be useful to tabulate the more exactly calculated magneton numbers expected from the different theories.

For the magnitude of the Bohr magneton $\left(N\frac{he}{4\pi m}\right)$, 5564 erg gauss^{-1} mol^{-1} has been accepted,[4] where the spectroscopic value of e/m has been used.[5]

The experimental Weiss magneton, in terms of which the measurements are usually described, has the value 1123·5 erg gauss^{-1} mol^{-1}. The ratio of the two units is 4·952.

Hund's theory leads to the formula $p = 4{\cdot}952\, g\sqrt{j(j+1)}$; the theory of Bose and Stoner to $p = 4{\cdot}952\sqrt{4s(s+1)}$.

The values of p for the group of rare earths (following Hund), and for the iron group, are tabulated next to the numbers, as given by the authors themselves.

RARE EARTHS.

Number Electrons.	Ion.	Basic Level.	p_H.	p_H foll. Hund.

Measurement of the Electricity Liberated during the Downgrade Reactions of Organic Compounds.

THE possibility of deriving electrical energy from an organic reaction proceeding irreversibly in one half-element of a cell seems so unlikely on general grounds that an attempt has been made to repeat the observations recorded by Prof. Potter under the above title in NATURE of April 11. Briefly, Prof. Potter found that if the cell

carbon (or stainless steel)	dilute HCl	porous pot	CuSO4 solution	copper

is short-circuited, no current passes; if, however, zinc is placed in the acid out of contact with the electrode, copper is deposited on the right-hand electrode so long as the zinc continues to dissolve. He further found that, if the acid is replaced by 15 per cent sugar solution and the cell is short-circuited, copper is deposited on the electrode as soon as yeast is added to the sugar solution, but not before. Prof. Potter also found that a primary cell (capable of electrolysing copper sulphate solution) is obtained from the combination

carbon	15 per cent sugar solution	porous pot	15 per cent sugar solution and yeast	carbon

the electrode in the fermenting half of the cell being negative. Observations were further recorded in which the decay of lawn mowings and other organic matter was made to produce electrolysis.

When I repeated Prof. Potter's experiments with the first type of cell, I found small random changes in weight of the copper electrodes which, however, were affected neither by the addition of zinc to the acid nor by the addition of yeast to the sugar solution. Furthermore, control copper electrodes, immersed in the copper sulphate solution but unconnected to the other electrode of the combination, showed exactly similar changes in weight.

To explore the matter further, the cell

carbon	$\frac{N}{5}$ HCl	saturated KCl	$\frac{N}{5}$ CuSO4	Cu

was set up and its E.M.F. was measured on a potentiometer. The cell was found to give a substantial but variable E.M.F. ranging from 0·1 to 0·3 volt; the carbon electrode was usually positive, so that if the cell had been short-circuited, copper would not have deposited but would have dissolved. When zinc was placed in the acid, its solution caused no substantial change in the sign or magnitude of the E.M.F.

The replacement of the acid by 15 per cent sugar solution yielded a cell in which the carbon was positive to about the same extent. The addition of yeast and subsequent fermentation produced none but random variations in the E.M.F. of the combination.

The cell

carbon	15 per cent sugar solution	porous pot	15 per cent sugar solution and yeast	carbon

was set up several times. It yielded an initial E.M.F. entirely fortuitous in sign and upon which the subsequent fermentation produced no systematic effect. Like all the other combinations measured, this cell polarised with great readiness.

In none of my observations is there any evidence, therefore, of a continuous supply of electrical energy from a chemical reaction proceeding irreversibly. Neither the solution of the zinc nor the fermentation of the sugar had any effect on the E.M.F. of the cell beyond the random effects to be anticipated during the liberation of gases in the neighbourhood of an indeterminate and readily polarisable electrode such as carbon.

Since making these observations I have been in correspondence with Prof. Potter. We have not succeeded in discovering any significant discrepancy in the two sets of experimental conditions beyond the fact that I used pure sucrose while Prof. Potter used unrefined sugar. Apart from their effect on the internal resistance of the cell, it seems unlikely that the impurities could play a decisive part.

X-Ray Fibre Photography.

We have recently brought to a successful termination an investigation which was carried out to determine a combination of an X-ray generating plant and tube which would enable fibre photographs to be taken with exposures so low as to enhance the value of X-rays as a testing medium in the silk, wool, and allied industries. Fig. 1 is an X-ray photograph of ramie fibre of fifteen minutes' exposure. This exposure, however, greatly under-estimates the efficiency of the plant, since later photographs were produced with exposures of only thirty seconds' duration. This was repeated for wool and artificial silk.

A Laue spectrographic arrangement was used, and the fibres were subjected to copper radiation emanating from a Muller type water-cooled hot filament tube working at 10 m.amp. at 40 k.v. peak. The tube was fed by a D.C. generating plant consisting of a valve rectifier plant with smoothing condensers, arranged for an output of 30 m.amp. at 60,000 volts D.C. maximum.

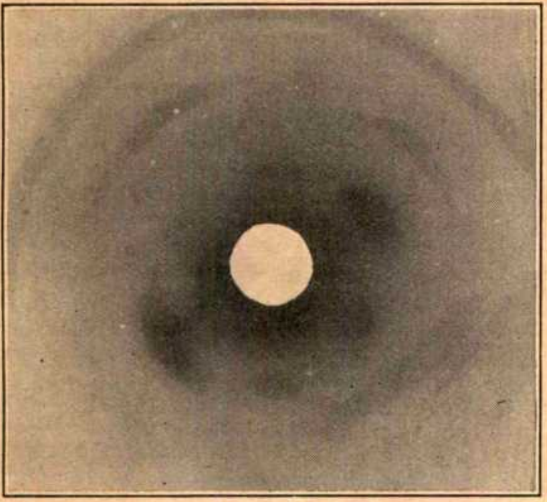

Fig. 1.—X-ray photograph of ramie fibre. The outer ring is due to brass of collimating tube.

We intend in the future to use a helium-filled Muller chrome iron tube with flat copper anode and fitted with four Lindemann windows. This tube will carry continuously, on rectified current, loads of 25 m.A. at 60 k.v. peak or 30 m.A. at 40 k.v. peak. This results in a treble output of that initially used, and in addition the tube is so designed that the anode to fibre distance is reduced by half. Thus we confidently expect to obtain X-ray fibre photographs with exposures of five seconds and even less.

"The World List of Scientific Periodicals."

"The World List", of which the first edition was published a few years ago, was an attempt to issue a complete alphabetical list of all the periodicals in all countries publishing the results of scientific research, in existence between 1900 and 1920, with standard abbreviations for the titles of each. The List contained the titles of approximately 24,000 periodicals. It was impossible that a work so costly to compile and to print could be self-supporting, and the publication of the first edition was made possible only by grants from the Carnegie United Kingdom Trust and from private individuals.

The Royal Society of London, recognising the value to science of "The World List", has made a grant sufficient to enable us to undertake the preparation of a new edition. This is to be complete, so far as we can make it, up to the end of 1931. I shall be very grateful if librarians and others who have the first edition will send to the editor, Mr. W. A. Smith, Department of Printed Books, British Museum, Bloomsbury, London, W.C., a note of any errors they may have observed in the first edition, any omissions from it, and the titles of any existing periodicals containing the results of scientific research, in actual existence from 1900 up to the present, and omitted from the original edition.

P. Chalmers Mitchell
(Chairman, "The World List").

'All or None': a Question of Nomenclature.

The 'all or nothing' hypothesis represents such a clear-cut principle in elementary physiology that it seems a pity that the ambiguous phrase, 'all or none', should so often be used instead. We have been accustomed to suppose that a given physiological unit, or set of units, shows either 'all or nothing' of the response it can make under given conditions; also that additions to this response, under the same conditions but with greater stimulus, can be made only by co-operation (or, in a special context, 'recruitment') of additional units. This meaning is actually excluded by the nickname 'all or none', because we have supposed that 'some' units, few or many, fill in intervening stages of intensity of the response.

Moreover, recent and well-known work (such as the experiments at Oxford and at Cambridge on the spinal flexion reflex and on variation of electrical rhythm in sensory and motor units) demonstrates that 'all or none' of the active units can together modify their response. The alternative phrases now suggest two different principles, separately demonstrable in certain experiments—variability in number of units, each contributing its own 'all or nothing', and secondly, variability of contribution from 'all or none' of them.

Polarisation of Raman Scattering by Hydrogen Gas.

The theoretical work of Hill and Kemble, Manneback, and others, indicates that in the spectrum of the light scattered transversely by diatomic molecules, the rotational lines should be very imperfectly polarised. The Raman spectrum of hydrogen offers a particularly favourable case for an experimental test of this point, as the individual rotational lines are well separated from the exciting line. Working at a pressure of 50 atm. I have observed that the Raman lines representing the rotational transitions $0\rightarrow 2$ and $1\rightarrow 3$ in hydrogen gas are only weakly polarised, that is, to the extent of about 25 per cent; and that, on the other hand, the polarisation of the vibration lines appears to be sensibly complete.

By improving the experimental arrangements it has been found possible to eliminate stray light, and thus ensure that the light entering the spectrograph is exclusively that scattered by the molecules of the gas. Experiments are in progress to determine directly from the spectrograms the relative intensities of the Rayleigh and Raman scattering by various gases.

Yaksas.—In '*Yaksas*', pt. 2, published by the Smithsonian Institution, Freer Gallery of Art, Dr. Ananda Coomaraswamy continues his study of the Yaksas cults of India. All Yaksas, great or small, are vegetation spirits directly controlling, or bestowing on their *bhaktas*, fertility and wealth. All Yaksas are intimately connected with the waters; for example, Kubera's inexhaustible treasuries are a lotus and a conch; innumerable Yaksas have a makara or other fish-tailed animal as their vehicle; Kamadeva has the makara as his cognisance; the greater tutelary Yaksas control the rains essential to prosperity. In the decorative art, vegetation is shown either springing from the mouth or navel of a Yaksa, from the open jaws of a makara, or other fish-tailed animal, or from a conch, but never directly from a symbol representing the earth. But the Yaksas do not so much control the waters as water, as the essence in the water, which is at one with the sap in trees, the elixir of the Devas, especially Agni, with the soma, and the seed in the living being. They are a far greater and mysterious power, and far more significant than the Nagas or dragons. who are also water deities. The importance of the Yaksas in what has been called the Life cult is to suggest that this cult, which is connected with the worship of the Great Mother, may have been the primitive religion of India. A belief in the origin of life in the water was common to many ancient cultures, and must have arisen very naturally in the case of peoples, like those of the valleys of the Euphrates, Tigris, or the Indus, among whom water, whether of the seasonal rains or the overflowing river, was the most serious prerequisite for vegetal increase.

Hand-Spinning in Egypt and the Sudan.—The Bankfield Museum, Halifax, has published as No. 12 of the second series of its *Museum Notes*, a study of hand-spinning in Egypt and the Sudan, by Mrs. Grace M. Crowfoot. In this area a number of different types is found, from the most primitive and simple by hand alone to the highest type of suspended spindle-spinning reached before the invention of the wheel. Six types are recognised: (1) Hand-spinning alone, the simplest method known, in which the hand alone is used or with the assistance of the thigh. There is no example in modern Egypt, but it is represented in ancient Egypt. In the Sudan it occurs far to the south among the primitive Nuer. (2) Spinning by twisting a hooked stick, a simple and primitive method found among the conservative nomads, such as the 'Beit Awad' of the Beni Amer. (3) Spinning by rotation of the spindle in the hand, a surprising and beautiful method found among the Sudanese Arab tribes and the Hadendoa of the Red Sea coast. The stick is sometimes plain, and sometimes has a whorl at the tip. Its special value lies in its command over short-stapled wool. (4) Grasped spindle, in which a prepared rove is passed through a ring over a forked stick or other support and is spun on a large spindle suspended in both hands, known only from ancient Egypt. (5) Supported spindle: (*a*) spindle rests lengthwise on the right thigh and is spun on a large spindle grasped in both hands; (*b*) spindle spun while standing erect on the ground or in a shell or bowl; 5 (*a*) is used chiefly for cotton—the only modern example is in Dongola Province; 5 (*b*), the chief way of spinning cotton in many parts of the world, is used in the Sudan only by immigrants from Sokoto and Bornu. The flax-spinning of modern Egypt shows the influence of ancient Egypt and Europe, cotton-spinning in the Sudan shows strong resemblances to the flax-spinning of ancient Egypt.

The Wolf of Corea.—In Corea a considerable amount of damage is still caused by wolves, and the Tyosen (Corean) Government reports show that rewards are paid annually for the slaughter of more than a hundred individuals. On three occasions, Yoshio Abe visited Corea for material to study the wolves of the region, and these he now describes as belonging to a geographical race of the common wolf, *Canis lupus coreanus*. From the races of the common wolf which inhabit various areas of Asia, the Corean form is distinguishable by the relative slenderness of the muzzle, a character in which it approaches the North American *Canis occidentalis*. In colour, the Corean wolf, which, like other wolves, shows distinct variation in individuals, falls between the common wolf and the pale *Canis laniger* (*Jour. Sci., Hiroshima Univ.*, Ser. B, Zoo.; Dec. 1930.)

New North and South American Ascidians.—Dr. Willard G. Van Name in the *Bulletin* of the American Museum of Natural History, vol. 61, art. vi. pp. 207-225, describes four species of ascidians new to science, and a fifth from Tortugas, Florida, appears to be identical with a Japanese form, *Botryllus primigenus* (Oka), described by Prof. Oka in 1928. This species is noteworthy in that the branchial sac has but 4 rows of stigmata, unlike all other known American and European forms, which have 8 or more such rows—8 or 9 in the common *B. schlosseri*, typical of British waters. In addition the atrial orifices of some of the zooids of *B. primigenus* open directly on to the surface of the colony without the intervention of common cloacal cavities. Of the four species new to science, all are members of well-known families and genera: *Clavelina huntsmani* from the west coast of N. America; *Stolonica zorritensis* from Zorritos, Peru, peculiar in having a small number of gonads all apparently hermaphroditic; *Pyura bradleyi*, also from Zorritos; and *Polyandrocarpa gravei*, a compound styelid of flat encrusting form from Tortugas. As is usual with Dr. Van Name's publications, the descriptions of the species are accompanied by numerous helpful illustrations.

Antarctic Alcyonaria, Madreporaria, and Antipatharia.—Sir J. Arthur Thomson and Miss Nita Rennet describe these cœlenterates of the Australasian Antarctic Expedition, 1911–14, under the leadership of Sir Douglas Mawson (*Scientific Reports*. Series C, Zoology and Botany. Vol. 9, part 3, January 1931). The collection includes 31 species of Alcyonaria, of which 7 are new, 5 species of Madreporaria, and 2 species of Antipatharia. The most important find is that unique type of alcyonarian *Ainigmaptilon haswelli* Dean, placed provisionally in the Pennatulacea and already described in the *Proceedings* of the Linnean Society (Zoology, vol. 36; 1926) by Miss Isobel Dean. From a narrow main stem, without an axis, numerous short side-branches are given off which subdivide irregularly into twigs bearing many small autozooids. There are four longitudinal septa in the main stem—the most striking pennatulid feature—and the side branches are most nearly comparable, though not identical in structure, with the pinnæ of the pennatulids *Virgularia gustaviana* and *V. halisceptrum*. However, there is no satisfactory evidence of siphonozooids; also a definite axial canal and an axis are missing. It is, however, possible, although not probable, that the axis was separated from the colony in the dredging, as the septa are torn. *Ascolepsis splendens*, a new genus, is a beautiful alcyonarian belonging to the Primnoidæ in the order Axifera. This has a new type of sclerite, chalice-like in shape. Another species belonging to this genus. *A. spinosa*, is also described, and a form intermediate between these two. The plates are excellent, especially those which are delicately coloured.

Chromosome Multiples in *Chrysanthemum* and *Potentilla*.—IN a paper just received, N. Shimotomai (*Jour. Sci., Hiroshima Univ.*, Botany, vol. 1, p. 37) describes three species-hybrids of *Chrysanthemum* and the behaviour of their chromosomes. In *Ch. Decaisneanum* ($n=36$) × *Ch. indicum* ($n=18$) the F_1 hybrid has 54 chromosomes, which form 27 pairs in meiosis, and the pollen grains receive 27 chromosomes. This is presumably because 18 of the chromosomes from the octoploid *Ch. Decaisneanum* pair with each other. Similarly, in *Ch. marginatum* ($n=45$) × *Ch. morifolium* ($n=27$) the hybrid has 72 chromosomes which form 36 pairs. Again, 18 chromosomes of the higher polyploid parent mate with each other. In *Ch. marginatum* × *Ch. indicum*, however, the 63 chromosomes of the hybrid form 18 bivalents and 27 univalents. These hybrids are all intermediate between the parents, but nearer that one with the higher chromosome number. Another paper in the same journal (p. 1) gives chromosome counts in a number of further species of *Potentilla*, and discusses the phylogeny of the genus in the light of the chromosome numbers. It appears that primitive species and subsections have the basal number ($2n=14$) or low multiples; while in the Hæmatochroæ, regarded as recent in origin and arising in part through hybridisation, the numbers range from 42 in *P. nepalensis* to 112 ($16n$) in *P. hæmatochrus*. It is believed that the originals of *Potentilla* were diploid species with a circumpolar distribution in the Tertiary, whence they afterwards moved southwards, intercrossed, and gave rise to various polyploid species and groups.

The Classification of Carbonaceous Minerals.—In 1927 Prof. G. Hickling plotted the percentages of carbon and oxygen recorded in more than a thousand analyses of American and British coals, and found that the points lay on a well-defined and continuous belt covering the whole range from lignite to anthracite, thus demonstrating that these coals are members of a natural, unbroken series. Prof. H. Briggs has now plotted the corresponding data for other carbonaceous materials and recorded the results in the *Proc. Roy. Soc. Edinburgh*, **51**, 1931, pp. 54-63. It appears that there are two kinds of cannel coals, the analyses of which fall on distinct 'development' lines. In order of increasing hydrogen, the series recognised are (*a*) sub-cannels, (*b*) cannels, (*c*) paraffin shales, and (*d*) torbanites. These give lines nearly parallel to the coal belt, and beyond them fall two groups of crude petroleums, heavy and light oils respectively, on lines having a very different slope. It is noteworthy that the further from the coal belt an analysis is situated (in the direction of increasing hydrogen) the more suitable is the mineral as a source of oil. The graphs therefore serve a useful purpose as a standard of reference for distinguishing suitable materials for distillation.

High Vacua.—In the June issue of the *Journal of the Franklin Institute*, Dr. S. Dushman, of the research laboratory of the General Electric Company, reviews the advances in the production and measurement of high vacua which have taken place since the issue of his own and of other books on the subject, published five or six years ago. The chief advances are in the introduction of vapour pumps of much higher speeds, the use of what are known as 'getters' to improve the vacuum, and in the more careful investigation of the behaviour of the metal parts of the apparatus towards the vacuum. The usual method of measuring the speed of exhaust depends on Knudsen's expression for the resistance a tube offers to the flow of gas through it. Condensation pumps are the rule, and the Payne two-stage pump used by the Company is described. It requires a force pump giving a pressure of 2 mm. of mercury, and its speed is given as 60,000 c.c. per second. Pumps using organic liquids instead of mercury, as used in the Eastman Kodak Laboratories, are also described. Magnesium and calcium are the usual 'getters' for oxygen, but for hydrogen and nitrogen, cæsium and sodium are more active. Pressure gauges are generally either of the ionisation type, depending on the ionisation produced in the residual gas by accelerated electrons from an oxide-coated filament, or they utilise the temperature or resistance of a thin wire electrically heated in the residual gas. The author collects a considerable amount of information recently obtained on the constitution and amount of the gases in metals and in glass.

Reflection of Water Molecules at the Liquid Surface.—Whilst it is relatively easy to investigate experimentally problems connected with the emission and reception of charged particles, the study of the corresponding processes for neutral atoms and molecules often presents considerable difficulty and has received less attention. Prof. T. Alty has contributed a paper to the June issue of the *Proceedings of the Royal Society* in which he describes a determination of the reflection coefficient of water molecules when they are incident on a liquid water surface. The method employed was to measure the rate of evaporation from a water surface of known area as a function of the vapour pressure over the evaporating surface, whence by extrapolation to zero pressure the rate of evaporation into a vacuum could be deduced. The last quantity was then compared with the rate at which molecules struck the surface from the saturated vapour, calculated by the usual kinetic theory relations. The two quantities were of a different order of magnitude, and to reconcile them it is necessary to assume that the large majority of the molecules are reflected from the surface when they strike it, and pass back into the vapour phase. Under the conditions used by Prof. Alty, it appears that only about one per cent of the incident molecules are able to enter the liquid. The average time which a molecule spends in the surface is not greater than about 10^{-5} sec.

Photochemical Decomposition of Hydrogen Iodide.—The decomposition of hydrogen iodide gas on exposure to light, first studied by Lemoine in 1877, has been investigated several times, and it has been considered that the gas exhibited continuous absorption to a wave-length of 3600 A. In the May number of the *Journal of the American Chemical Society*, Rollefson and Booher show that the absorption extends as far as 4000 A. The absorption on the long wave-length tide of 3120 A. is interpreted as due to dissociation of the molecule into normal atoms (a type of reaction not very common), that on the shorter wave-length side giving an excited iodine atom. Salant and Sandow have reported decomposition with the 4047 A. line of the mercury arc. The conclusions are based on the value 69,000 gm.cal., or 3 volts, for the heat of dissociation into normal atoms, and the energy 0·95 volt to raise the iodine atom to the first stage of excitation. This gives the corresponding wave-lengths 4120 A. and 3120 A. The results are interpreted in terms of potential energy curves. It is concluded that in the zero and first vibrational levels the molecule may be considered as an example of ionic binding.

Estimation of Bromine in Organic Compounds.—By substituting butyl alcohol for ethyl alcohol in Stepanoff's method for the determination of halogens in organic compounds, Dr. F. Schultz claims to have made the method more accurate and even applicable to the determination of bromine in highly brominated hydrocarbons. Stepanoff's method (*Ber.*, 1906, 39, 49) of estimating halogens by treating the substance in alcoholic solution with sodium, thereby converting the chlorine, bromine, or iodine present into the sodium salt, possesses obvious advantages over the Carius tube method. Various modifications have been suggested from time to time, but the method has not hitherto been considered accurate for highly brominated hydrocarbons. In his paper in the May number of the *Collection of Czechoslovak Chemical Communications*, Dr. Schultz describes how he carried out the reaction by gradually adding sodium to the boiling butyl alcohol solution of the bromine compound. Hexabromobenzene, pentabromotoluene and hexabromonaphthalene were examined. After the sodium had all been introduced, boiling under a reflux condenser was continued for an hour. Water was then added before filtration and the acidified solution was precipitated with silver nitrate and 'back-titrated' with ammonium sulphocyanide. The results were in very good agreement with the theoretical values.

Oxidation-Reduction Potentials in Bacteriology.—It is now well known that living cells require a constant hydrogen ion concentration in their environment if they are to live and function normally, and in higher animals mechanisms have been developed to maintain this concentration in the tissue fluids constant at a point close to neutrality. The reducing power of the environment is probably similarly regulated, a balance being struck between the reducing and oxidising tendencies just as there is a balance between the hydrogen and hydroxyl ions. The oxidation-reduction potential can be measured by suitable indicators or potentiometrically. L. F. Hewitt, in a publication, "Oxidation-Reduction Potentials in Bacteriology and Biochemistry", recently issued by the London County Council (pp. 70. Price 2*s*.), describes a series of investigations on the oxidation-reduction conditions produced by bacteria in the medium by which they are surrounded, and has found striking differences of behaviour between different micro-organisms. Thus aerobes are in general able to reduce ordinary aerobic culture media until a moderately intense reducing level is reached; anaerobes, on the other hand, cannot effect any reduction in ordinary aerobic cultures, but if the medium is partially reduced to begin with, for example, by exclusion of the oxidising effect of air, they are able to establish very much more intense reducing conditions than the majority of aerobes. Pneumococci, again, do not maintain the level of reducing intensity after the logarithmic phase of growth, highly oxidising conditions being gradually established owing to the formation of peroxide. The virulence of hæmolytic streptococci is maintained in culture by opposing the reducing effects of the organisms, through increasing their oxygen supply. It seems possible that a systematic classification of organisms will result from studies of the oxidation-reduction potentials in bacterial cultures.

Astronomical Topics.

Distance of the Great Nebula in Orion.—A *Bulletin* dated June 11, from Science Service, Washington, D.C., gives a summary of a new determination of the distance of this nebula, made by Dr. R. J. Trumpler at the Lick Observatory, and reported by him to the Astronomical Society of the Pacific at Pasadena. He states that three different methods give the distance as 1800 light-years, which is about three times as great as the value generally given; thus Kapteyn gave the parallax of the nebula as 0·0055″, implying a distance of 590 light-years. As there is evidence of association between the nebula and many of the bright stars in Orion, their distance is generally taken to be about the same; if the new distance applies to Rigel, it must be of extraordinary brilliance. The table in Russell, Dugan, and Stewart's standard work gives its absolute magnitude as − 5·8 with a parallax of 0·006″; at three times the distance it would have absolute magnitude about − 8·2. The new value gives the diameter of the nebula, neglecting its faint extensions, as 26 light-years. Dr. Trumpler has also investigated the colour of the stars in the nebula; he finds that they are slightly redder than stars of the same type elsewhere, which he ascribes to the absorptive effect of the nebula on their light.

The Cape Observatory.—The report of the Cape Observatory for 1930, which has just come to hand, states that the transit circle observations include the sun, Mercury, Venus, and Vesta (which is used to check the equator point), zodiacal stars, and stars south of − 30° Decl. down to mag. 7·5. There is the welcome news that the heliometer observations of the outer planets since 1897 will shortly be published. They are likely to help in the determination of Pluto's mass.

Proper motions of stars in the Cape astrographic zone are being deduced by comparing recent photographs, taken through the glass, with those taken several years ago.

The relative trigonometrical parallax of Nova Pictoris came out as − 0·013″. Another determination was made by co-ordinating the increase of brightness with the expansion indicated by the spectroscope. The value 0·0015″ was obtained, which makes the absolute magnitude at maximum − 7·9.

The report shows that even before the end of 1930 the Eros programme was in full swing; the most important southern observations would be those made in January and February.

1930 was the driest year at the Cape since 1841, the rainfall being 16·46 in. The extremes of temperature were 104·0° and 35·8°. the annual mean being 63·7°.

New List of Astronomers and Observatories.—Prof. P. Stroobant and the other members of the staff of Uccle Observatory have just published a new edition of their useful list. The first edition appeared in 1907 and is now out of date; the new one is brought out under the auspices of the International Astronomical Union, which has assisted in the cost of publication. Very full particulars are given of the observatories; the names of all members of the staff, the department that they are attached to; details about the instruments, and the work for which they are used. The list of astronomers has references to all the pages on which they are mentioned. Full details are also given of the astronomical societies, with a description of their special objects, their dates of meeting, their publications, etc. They are arranged in order of their dates of foundation, the Royal Astronomical Society coming first. Finally, there is a list of astronomical periodicals, with particulars about their special fields of work, dates of publication, and subscription prices. Altogether the volume is one which all astronomers will find most useful; it is printed and edited by Messrs. Casterman, Tournai; the price is not stated.

National Physical Laboratory, Teddington.

INSPECTION BY THE GENERAL BOARD.

ON Tuesday, June 23, the General Board of the National Physical Laboratory made its annual inspection of the laboratory. As is customary, a large number of visitors, including members of scientific and technical institutions, government departments and industrial organisations, were present and were received by Sir Gowland Hopkins, president of the Royal Society, chairman of the General Board, Sir Richard Glazebrook, chairman of the Executive Committee, and Sir Joseph Petavel, director of the Laboratory.

A comprehensive range of experiments and apparatus, illustrating the various activities of the Laboratory, was shown.

In the Aerodynamics Department, the compressed air wind tunnel, a model of which was shown in 1928, has nearly reached completion and was thrown open for inspection. This tunnel, which consists of a main steel shell 50 ft. in length and 17 ft. in diameter, enclosing the working tunnel of 6 ft. diameter, is constructed of rolled steel rings closed by hemispherical end castings, both made at the works of Messrs. John Brown, Ltd., Sheffield. The tunnel is of the open jet, return flow type and is capable of withstanding pressures up to 25 atmospheres. Three 400 h.p. compressors are housed in an adjoining room and can raise the pressure to its full value in about 80 minutes. The propeller for circulating the air is driven by an external 400 h.p. motor, the shaft passing through a stuffing box. It is anticipated that an air speed of about 90 ft. per sec. will be possible at the highest working pressure, corresponding to a speed of about 150 miles per hour in the case of an average aeroplane under normal atmospheric conditions.

In one of the four-foot wind tunnels demonstrations were given of the buffeting of aeroplane tails, a phenomenon revealed by tests subsequent to the Meopham accident. This phenomenon is due to the character of the airflow behind an aerofoil, when the latter approaches stalling incidence, particularly at high speeds. Under these conditions the airflow becomes periodic, and the eddies so formed may impinge on the tail, and in special circumstances may set up serious vibration. To demonstrate the phenomenon, an aerofoil was mounted in the tunnel at stalling incidence and means were provided of setting the tail in any desired position relative to it. The tail was provided with suitable flat springs to allow vibration to take place, the oscillations being projected by appropriate mirrors on to photographic paper. The investigation is directed to the study of the limits of the eddying wake produced by different wing sections at various angles of incidence, and to the buffeting effects on a tail placed at various positions inside and outside the wake.

Apparatus for the precise reproduction of the spinning motion of an aeroplane has been constructed in the Department. Hitherto, in wind tunnel tests relating to spinning problems, the model has been rotated about an axis through the centre of gravity. This does not take account of the fact that the latter moves in a helix. The new apparatus allows for this factor. The model is offset at any desired distance from the rotating axle by means of a radius arm, the rotation being effected by means of a motor and epicyclic gearing. The rolling moment is determined by measurement of the mechanical reaction on the gear system due to the model.

Of interest also was a method of rendering visible the airflow round a body placed in an airstream. Fine platinum wires, half an inch apart, are mounted on two vertical supports situated in front of the body and heated to redness by means of an electric current. Each wire gives rise to a band of heated air which persists for some distance downstream. These bands, owing to their decreased refractivity, cast a shadow on a screen when suitably illuminated and thus give a direct picture of the streamlines. These can be examined by means of a stroboscope if necessary. Such phenomena as the behaviour of an aerofoil at stalling incidence and of the Handley Page slot are clearly brought out.

In the Engineering Department an investigation was in progress for the Roads Department of the Ministry of Transport on the forces due to wheel impacts on a road. To determine such forces it is necessary to know the corresponding spring load and the linear accelerations of two points on the axle. To measure the latter, special accelerometers have been designed and constructed in the Department. These instruments depend on the variation of a mutual inductance by the impact. Alternating current of definite frequency is supplied to the primary coil and the secondary current, after rectification, is recorded by an oscillograph. The load on the springs is determined by mounting the normal suspension springs on stiff springs, the deflection of one end of which is determined by a method similar to that utilised in the accelerometers. The whole equipment is mounted on a special trailer, which is provided with a dark room for development of the records on the road. The effects of different types of tyre and sizes of wheel are being investigated.

In connexion with the investigation of the mechanical properties of materials at high temperatures, creep tests have been made on a variety of materials—cast and forged steels, alloy steels, and non-ferrous alloys—and the effects of an atmosphere of steam and of a hot air blast have been investigated. To obtain greater refinement in such tests, very accurate control of the temperature of the specimens has been found necessary. For this purpose a further batch of creep units has been constructed. These are controlled by a thermionic valve bridge and suitable relays, and the temperature can be maintained constant within ± 0·5° C. The extension of the specimen is measured by means of Marten's mirror extensometers, capable of measuring to one millionth of an inch on a five-inch length. A new 25-ton testing machine to accommodate the new creep units has been installed. With this machine low rates of creep can be obtained.

Attention has been given to a method of testing the hardness of thin coatings of electrolytically desposited metals such as chromium. Some success has been obtained with a diamond scratch method, using suitable loads.

Experiments have also been made to determine the minimum dimensions for correct results of a test piece suitable for use in ball indentation tests. Sample test pieces of various shapes and thicknesses which have been used in the investigation were on view.

Of interest also was apparatus for determining the hardness of white-metal bearings at temperatures up to 350° F. The tests are made on the metal in actual half bearings ready for service. A Vickers loading machine is used, the bearing being immersed in an oil bath mounted on the machine and maintained at the required temperature. The apparatus was shown in use for tests on a big-end bearing.

Attention has also been given to the problem of corrosion fatigue, which is being dealt with under two aspects. In one case experiments have been made on a single crystal of aluminium stressed while immersed in a slow stream of tap water. Corrosion was found to occur preferentially on the site of previously formed slip bands, and to this corrosion the ultimate failure of the crystal was mainly due. Specimen test pieces showing the corrosion product (aluminium hydroxide) were on view. In the second case the relative strengths of aircraft steels and alloys have been determined when tested *in vacuo*, in various gases, in a salt spray, and with and without protective coatings. The specimens are subjected to reversed bending and to reversed direct stresses under these conditions.

Research work has been carried out to determine the causes of failure of wrought iron chains. The investigation has shown that failure may be caused by the occurrence of burnt iron, which is due to an excess of phosphorus and silicon, and dates back to the puddling stage of manufacture. A test has been devised to reveal the presence of such defective material. Work is also in hand to determine the effects of service conditions and of subsequent heat treatment, such as annealing, upon the threaded parts of shackles and upon the pitch of chains. Special machines have been devised in which service conditions are reproduced.

The Department has been responsible for the design of standard forms of crane hooks. Sample hooks have been prepared and tested for strength and have been found extremely satisfactory. The designs have been adopted by the British Engineering Standards Association. Specimen hooks both before and after test were on view.

An investigation was in progress to study the velocity of travel and the wave-length of waves set up on the surface of water by the action of wind. The waves are produced in a 12 in. by 12 in. rectangular tunnel 50 ft. in length. By observation with a stroboscope it is possible to determine the frequency and wave-length at the same time. From photographs of the wave motion, scale models of the actual waves can be constructed and the distribution of wind pressure over them determined in a wind tunnel. The relation between the wave-length and the velocity approximates very closely to that calculated on the basis of the irrotational motion of a frictionless wind.

Of interest also was a liquid gauge used for simultaneous measurements of the wind pressure at a number of points on a building. The tubes contain benzyl alcohol and a solution of calcium chloride; these liquids give a clear surface of separation and the difference of their densities is small. A sensitivity five times that of the ordinary water gauge is attained. A flashlight photograph is taken of the gauge, and the pressures corresponding to different points of the building are read off from the print.

In the Metallurgy Department, research work was in progress in connexion with the effect of various aqueous solutions of salts, such as may be present in boilers, on the behaviour of boiler steels when stressed. Steel specimens which have been subjected to the action of various solutions are bent in alternate directions at intervals of 24 hours. It has been shown that the effect of continuous immersion in tap water is to reduce the survival of the specimens (expressed as the number of bends before fracture) by 30 per cent as compared with the endurance in air. Concentrated solutions of sodium chloride have a similar but less severe effect.

The investigation of the effect of flue gases, mentioned last year, has been continued, and has now reached the stage when a batch of a dozen wires can be tested simultaneously for the corrosive action of flue gases. Improved apparatus has been installed, permitting the tests to be carried out at 400° C., 500° C., and 600° C.

An investigation has been undertaken on behalf of the Aeronautical Research Committee in connexion with the constitution and structure of magnesium alloys. The work is directed towards improvements of mechanical properties by the discovery of new alloys in which there is a considerable solubility of the added element, or a change of solubility with temperature sufficient to permit age hardening. Samples of such alloys were on view.

Beryllium is usually prepared by electrolysis of its fused chloride at white heat. A method has, however, been developed in the Department for the electrodeposition of the metal from its fused salts at a much lower temperature. Coherent deposits on copper have been obtained in this way and specimens were exhibited.

Research work has been undertaken for the British Non-Ferrous Metals Association to determine the effects on the strength of copper of such impurities as bismuth, arsenic, antimony, and oxygen. Prepared specimens in the form of strips are subjected to bending in alternate directions in a special machine.

One of the difficulties encountered in the determination of the melting points of some alloys is the presence of vapour, which prevents the use of an optical pyrometer and may contaminate thermocouples. To avoid this difficulty, work is in progress to produce special refractories which are impervious to such vapour. It has been possible to make small tubes of glazed alumina which are satisfactory in this respect, and work is in progress to apply the technique to the production of larger tubes. To avoid glow discharge, and hence error in the thermocouples due to local heating when these are used in the induction furnace, a special furnace of this type has been evolved. This is coreless and is fitted with a water cooled electrostatic screen round the melting chamber.

A demonstration was given in the rolling mill of a special type of failure which can occur in the rolling of ingots of aluminium alloys if the conditions of cooling are not correct. These alloys are rolled while hot. Accurate control of the temperature and the conditions of working previous to rolling—such as casting and forging—are essential.

In the Metrology Department a new clock has been installed depending for its action on the mechanical vibrations of a metal bar held at its centre. The primary vibrating element is a rod of elinvar, an alloy with a low-temperature coefficient of elasticity. This is maintained in a state of self-vibration by the application to one end of electrostatic forces obtained after amplification by a valve amplifier from similar feeble forces taken from the other end. A phonic motor operated by the amplifier drives a clock train, one spindle of which rotates once per second. Suitable means are provided for the recording of these seconds on a chronograph. To ensure constancy of frequency, the bar is enclosed in a special housing, the temperature and pressure in which can be controlled by immersion in a vessel of circulating water, the temperature of which is regulated by a toluene thermostat.

Of interest also was a new method of testing surface plates. The plate to be tested is supported on a somewhat larger one provided with levelling screws, and resting on a large flat plate forming the base of the apparatus and carrying a 'Hirth' minimeter as an indicator. The specimen is first set approximately parallel to the base plate by means of the minimeter and then explored by the same instrument. If a standard plate, of which the departures from flatness are known, is substituted for the test plate and the same procedure is adopted, the errors in the latter can be readily determined.

In the Physics Department the investigation on the heat transfer from moving air to cold pipes has been continued, and extended to include banks of pipes such as are used industrially for air cooling in refrigerators.

Experiments were in progress to determine the heat transmission through wall materials. A specimen plate of the material is laid on an electrically heated plate, backed with cork, and is surmounted by a water plate. The electrical input, after correction for the heat conducted through the cork, together with the temperatures of the two faces, gives the necessary data for calculating the conductivity of the material.

The thermal conductivities of heat-insulating materials at high and low temperatures were also under investigation. In the case of the low temperature measurements, the method adopted is similar to that used for the wall materials, a refrigerating plant being utilised for the maintenance of the low temperature. For the measurements at high temperature a water-flow calorimeter is used. The rate of flow, and the rise of temperature of the water when steady conditions have been attained, give the data for the calculation of the thermal conductivity.

An investigation is being carried out, for the Atmospheric Pollution Research Committee, in connexion with the determination of the water in fogs, and a dew point method has been developed for the purpose. A stream of fog-laden air is drawn through a heated tube to vaporise suspended water droplets, and the dew point of the resultant fog-free air is then determined. For the production of artificial fogs a special equipment has been devised consisting of a small chamber provided with air-circulating apparatus which is supplied with steam from an external generator.

A study has also been made of the basic laws of the wet and dry bulb hygrometer over the temperature range 40° C.–100° C. As standards of reference the dew point and gravimetric methods of determining humidity have been used. Apparatus has been designed to give a stream of air at any desired temperature and humidity flowing past the wet bulb thermometer, with velocities exceeding three metres per second. A number of novel features have been incorporated in the apparatus.

In the Sound Division attention is being devoted to the increasingly important subject of noise measurement. The laboratory has co-operated with the Royal Aircraft Establishment in connexion with measurements of the noise of airscrews and exhausts. In the case of the former, the effects of tip speed of rotation, blade diameter and blade shape have been studied and have yielded interesting results. An investigation has also been undertaken for the Ministry of Transport on the noisiness and stridency of motor horns. The loudness was measured by means of an audiometer of the Barkhausen type. By means of a portable microphone amplifier arrangement and cathode ray oscillograph, measurements were also made of the spectral distribution of the sound intensities emitted by the horns. The results indicated that some of the factors affecting the stridency might be the occurrence of strong high frequency components and the presence of inharmonic series of frequencies.

In the Radiology Division the depth below the surface of the cathode at which X-rays originate is being explored. A special hot-cathode X-ray tube is used, the target consisting of thin foil of the material to be investigated. The nature of the X-ray output is analysed by comparative measurements of the absorption in an ionisation chamber.

A number of investigations are being undertaken in connexion with the application of X-rays to industrial problems. These include a study of tungsten steels and tungsten steel residues, the effect of rolling on the crystal orientation in aluminium, and of drawing on that in constantan wire, problems of electrodeposition, paints, and artificial teeth. In the case of constantan wire, the temperature coefficient was found to change as the wire was drawn, and the effect on this phenomenon of changes in crystal orientation is being studied.

In the Electrical Standards Division considerable attention has been devoted to the development of a standard of radio-frequency of high accuracy. The requisite precision has been attained by the use of a valve-maintained tuning fork operating in an airtight enclosure in which the pressure and temperature can be maintained constant. The six walls of the enclosure are provided with heating mats, temperature control being effected by means of a toluene thermoregulator. The tuning fork controls a phonic motor and chronograph, on which are recorded hourly the differences of the fork and the standard Shortt clock. The electrical and mechanical arrangements are such as to permit the determination of the frequency of the fork at any time to an accuracy of two parts in ten millions.

A method has been evolved for the measurement of the small anode-grid capacity of screen grid valves. Use has been made of the amplification of the valve itself. A tuned circuit, the coil of which is loosely coupled to a radio frequency generator, is inserted between the grid and the filament, resonance being indicated by a valve voltmeter. Readings of the condenser in the tuned circuit with no impedance, and with high impedance in the plate circuit, enable the anode-grid capacity to be determined.

An investigation has been commenced in connexion with the magnetic susceptibility of various rocks on behalf of the Geological Survey of Great Britain. An instrument of the type used by Prof. E. B. Wilson has been designed for the purpose. The specimen, in the form of a cylinder, is suspended at the end of a torsion arm in the gap of a large ring electromagnet. The instrument is capable of measuring susceptibilities one hundred million times less than that of iron.

For the precision measurement of the resistance and inductance of four-terminal resistances at power frequencies, a substitution method which avoids the necessity of taking current from the voltage terminals has been evolved in the Electrotechnics Division. The resistance under test is connected in series with a known standard resistance of nearly the same value and with the primary of a nickel-iron transformer. In series with the secondary is a resistance the value of which is so adjusted with reference to the transformer ratio that the voltage drop across it is approximately equal to, and may be opposed in turn to, that across each of the standard and test resistances. A vibration galvanometer is included in the apparatus and its deflection can be reduced to zero by suitable shunts incorporated in the secondary circuit. The resistance and inductance of the unknown resistance can then be determined.

Another exhibit showed arrangements for the measurement of the current rating of power cables. The modern trend in building construction has led to a more extensive use of electric power, and it is becoming standard practice to employ single core lead or rubber covered conductors to carry the current. Owing to sheath losses and skin effect, the current carrying capacity of a cable for a given temperature rise is less with alternating current than with direct current, and is determined by the maximum temperature rise that can be allowed in any given set of circumstances, having regard to the deleterious effect of high temperature on the properties of the insulating material. The object of the investigation is to determine the current carrying capacity of standard cables of various types and sizes under different conditions of laying, both for alternating and direct current.

For work in connexion with the testing of fuses, the laboratory facilities have been extended to cover the latest specification of the British Engineering Standards Association for domestic fuses up to 250 volts and 100 amperes. The specification requires that the tests be made at 260 volts and at suitable short circuit currents up to a maximum of 6500 amperes. With the new equipment, the short circuit is made from a distance by means of a solenoid controlled switch, the cut-out being observed through a wired glass panel in the door of the test enclosure. An auxiliary circuit incorporating a neon lamp indicates whether iron-clad cut-outs show any tendency to arc to their cases.

In the Wireless Division a new type of dynatron oscillator has been developed by the use of the negative resistance characteristic of the screen grid valve. By coupling the anode to the control grid through a small capacity and including a resistance of the order of a megohm in the filament-control grid circuit, higher frequencies than are possible with normal dynatron circuits have been obtained. The exhibit shown can be used for the generation of oscillations of wave-length as small as 6 metres.

The same principle can be applied to the problem of selective amplification. With the usual triode valve the presence of the positive shunt resistance of the valve decreases the selectivity of the tuning circuit through damping. If the negative resistance characteristic of the screen grid valve be utilised, the selectivity of the amplifying stage can be made greater than that of the tuned circuit alone. A demonstration of this was given by means of a circuit incorporating a valve of this type.

The investigation on behalf of the Radio Research Board in connexion with the development of transmitting and receiving apparatus for very short wave-lengths has been continued, and equipment capable of transmitting and receiving oscillations of wave-length as small as 1·5 metres was shown. The apparatus has been used for the study of the propagation characteristics of very short waves.

The apparatus for testing the performance characteristics of wireless receivers has now been extended to cover the shortest wave-lengths in commercial use. Improved apparatus has been installed capable of carrying out comprehensive tests at wave-lengths from 7 metres to 2000 metres. The tests comprise over-all sensitivity, radio-frequency, selectivity, and fidelity in the reproduction of radio-frequencies. The last-named test is carried out by the use of an input modulation free from harmonics. Any harmonics present in the output constitute a measure of the distortion produced.

In the High Voltage Building, equipment for the measurement of the dielectric loss of high voltage porcelain insulators was exhibited. Demonstrations were given of flashover tests to determine the maximum voltage withstood by a 132-kilovolt porcelain insulator string.

In the Photometry Division an investigation was in progress in connexion with the light-diffusing properties of diffusing glassware. These properties are governed by the size and concentration of the particles, and apparatus has been developed in the division for the measurement of these two quantities by the use of a powerful microscope. Half-silvered interferometer plates are fitted to the fixed and movable stages of this instrument, enabling the movement of the latter to be obtained directly in terms of light wave-lengths. The diameter of a particle can be determined by observation of the interference fringe system, as the particle is made to traverse a fixed cross wire, or alternatively by attaching the cross wire to a travelling microscope, the scale of which can be calibrated by means of the interferometer. To determine the concentration, the field is limited by an aperture of known diameter. The microscope is focused through the particles by a slow-motion device, the distance traversed being measured by a second interferometer.

The fundamental work on glare has been extended to cover the glare effect of coloured light sources with white and coloured backgrounds. Practical application has also been made of the results already obtained with normal light sources by the design of an instrument for the determination of the glare effect due to an actual lighting system. Two measurements of the brightness difference threshold, one with the glare sources exposed to the observer's eyes, and the other with the glare sources screened, give a ratio which is a measure of the glare effect.

In the William Froude Laboratory a model of a single-screw vessel was being tested to compare its behaviour in shoal and deep water. There are reasons for supposing that there is a scale effect leading to differences between the model and the full-sized ship. The model under test was equipped with its own inboard motor and propeller and apparatus for determining its resistance through the water. A model twin-screw vessel fitted with its own propelling and recording gear and utilised for research work on the backing qualities of propellers was exhibited. The tests are designed to show the thrust capacities of propellers of various shapes and diameters to destroy and reverse the motion of the model.

The International Congress of the History of Science and Technology.

THE Second International Congress of the History of Science and Technology, which assembled in London on June 29–July 4, has achieved a notable success, thanks to the untiring efforts of its distinguished president, Dr. Charles Singer, and the executive committee, and thanks also to the active interest it has aroused among scientific workers and historians throughout the world. The Congress, which was really the first of its kind, originated with the Comité International d'Histoire des Sciences, which was founded at Oslo on Aug. 17, 1928. It has, however, been fortunate in enlisting the co-operation of the Comité International des Sciences Historiques, of the American History of Science Society, and the Newcomen Society for the Study of the History of Engineering and Technology, of London. It has thus been possible to show, in its widest extent, the important part played by the sciences in historical and technical research. The papers and discussions of the Congress, and the large attendance of official representatives, who came not only from most of the universities of Great Britain and the Empire, but also from the Continent, North and South America, Asia, and Africa, bear witness to this fact.

At the inaugural session of the Congress, which was opened by the President of the Board of Education, the Right Hon. H. B. Lees-Smith, M.P., in the Great Hall of the Royal Geographical Society, Dr. C. Singer read some paragraphs of his inspiring presidential address on "The Beginnings of Science", which was published in full in NATURE of July 4. He emphasised the dynamic rôle of science, which is best illustrated by its history, and pleaded for the introduction into school-teaching of the broad lines of scientific history.

The work of the Congress itself was divided into four main sections, which met most fittingly in the lecture hall of the Science Museum. The first section, with Prof. G. Loria (Genoa) as chairman, dealt with "The Sciences as an Integral Part of General Historical Study". In his opening paper, Prof. G. N. Clark (Oxford) showed the complexity of the relations between the history of science and general history, and claimed that science has more truly a history than have other human activities, owing to the fact that the history of science is distinguished by more definite achievements and a more orderly development. This point was further emphasised by Sir William Dampier-Whetham (Cambridge), who proposed that the teaching of history should follow the natural order of its development, moving onward from primitive emotions to law, economics, and science. In support of these views, Dr. T. Greenwood (London) maintained in his paper that even the development of mathematics is a necessary constituent of both philosophy and technology, and illustrated the point that a critical history of mathematics should help in getting a deeper knowledge of the various philosophical systems which, in turn, provide the fundamental causes of the periodical and progressive changes in the mental and material outlook of the human race. Some stimulating remarks were made in this connexion by Prof. A. V. Hill (London), who submitted that if history is to deal with human greatness, with things which have given man control of himself and his surroundings, that have relieved him of superstition, ignorance, ill-health, and incompetence in the face of natural forces, then the great figures of science and their discoveries deserve a more worthy place even in children's history-books. For after all, the forces that move us are forces of our own making, which cannot be of less importance than the results they produce.

To this individualistic interpretation of history and to the paramountcy of the history of science, the representatives of the U.S.S.R. took exception, and proposed instead a communistic explanation of scientific development, in which the integrative work of the masses is exalted at the expense of the glorification of genius. Prof. B. Zawadovsky (Moscow), for example, does not conceive history as the history of personality, but rather as the process of development of mankind conforming to certain laws, as a social whole in all the multiformity of its class structure. From this angle, the history of science begins only from the moment when we discern the particular conditions of material culture and the economic requirements of production which determine the direction of the interests of the scientific workers concerned, and the readiness of society to utilise their discoveries. In seconding this opinion, Prof. E. Colman (Moscow) was able to illustrate the influence of the spiritual atmosphere of his time on Darwin himself by means of a letter written by the great naturalist to Karl Marx, in which Darwin admits having refrained from writing on religion in order to avoid surprising his contemporaries and his relatives, although he was all the same an advocate of free thought on all subjects. Prof. M. Rubenstein (Moscow) shared the views of his colleagues, suggesting that history has not been made by great men, but by the economic and social forces of which they have been the expression. It might be said here that the attitude of the Soviet delegates can scarcely explain any history, however stimulating their message and their endeavours to put it into practice in their own educational institutions.

The second section of the Congress, with Prof. W. H. Welch (United States) in the chair, discussed the important problem of "The Teaching of the History of Science". M. Aldo Mieli, the active permanent secretary of the Comité International d'Histoire des Sciences and editor of *Archeion*, told the Congress how this body is directing an inquiry into the teaching of scientific history, which will be completed in time for the Congress of History to be held at Warsaw in 1933. Going into the heart of the debate, Prof. A. E. Heath (Swansea) tried to show that our social and cultural disharmonies are largely due to our failure to acclimatise ourselves to modern cosmologies; and proposed, as a solution of this difficulty, the creation of a scientific history more in accord with the facts of the modern world. On the other hand, in advocating the development of special courses in the history of science in secondary schools and colleges, Prof. F. S. Marvin (University of Cairo) outlined, in his paper, the advantages to be gained by introducing the historical side into scientific work: such a method would present science as a growing thing; it would show the link with the other aspects of our knowledge; it would present the mass of scientific facts in a more human form; and finally it would illustrate the collective work of the human mind, building up an increasingly coherent framework of the universe. One may add, too, that the history of science can suggest new lines of research, and thus lead to unexpected discoveries.

Prof. A. Wolf (London) outlined the teaching of the history of science in the University of London, which owes so much to his own efforts, pointing out as one of the difficulties of the organisation of such courses the existing hostility towards new subjects, which are wrongly imagined by many to be side lines to something else. Prof. P. Diepgen (Berlin), Prof. H. Dannemann (Bonn), Prof. Q. Vetter (Prague), Prof. M. Stephanides (Athens), and Prof. D. E. Smith (United States) gave some interesting details about the teaching of the history of science in their respective countries; while Prof. Laignel-Lavastine, the new holder of the chair of the History of Medicine in the University of Paris, expressed the feeling of the whole Congress when he urged the necessity of university chairs of the history of science in the principal universities of the world.

The third section of the Congress was devoted to the "Historical and Contemporary Inter-relationship of the Physical and Biological Sciences", and was presided over by Prof. W. Ritter (United States). It developed into a lively debate between 'organicists', represented by Prof. J. S. Haldane, Prof. D'Arcy Thompson, Dr. E. S. Russell, and Mr. L. L. Whyte, and the 'mechanists', represented by Dr. J. Needham, Dr. J. H. Woodger, Prof. L. Hogben, and Prof. Baas-Becking (Holland). The case for organicism was put forward forcibly by Prof. J. S. Haldane (Oxford), who claimed the independence of biology from physics, while admitting that the advances of physics during the present century have made it much easier to realise the true relations between these sciences. The discovery that atoms are not mere inert elastic bodies, but centres of intense specific and persistent internal activity, and that on this internal activity their physical and chemical properties depend, has upset the physical conceptions which we inherited from Galileo and Newton. Atoms seem now as if they had properties similar to those which the vitalists attributed to living organisms. Yet, on the other hand, biology deals with parts and events which are manifestations of the co-ordinated whole which we call the life of the organism. Hence, it looks as if, while we shall retain the old physical and mathematical conceptions for practical purposes, the more fundamental physical and mathematical conceptions are assuming characters similar to those of biology. This fundamental attitude was further explained by Mr. L. L. Whyte, who showed how the study of the structure of material bodies and of radiation is beginning to influence biology. The adequate description of ordered structures, which was impossible by classical methods, is now expressed by ' quantum conditions ' which refer to systems as a whole, each part having in it definite positions and motions. Thus the conflict between the analytical methods of classical physics and the organic concepts of biology is thinned down to such a point that it may be hoped to see the study of biology leading ultimately to the discovery of exact biological laws defining the structural characteristics of living systems.

Dr. Needham's cry for an increase in the use of the style of physics in biology, and Dr. Russell's slogan, 'Back to Aristotle', alike strengthened the resistance of the mechanists, who, like Prof. L. Hogben (London), emphasise that there was never a time when biologists entertained more confidence in the usefulness of classical physico-chemical methods as instruments for arriving at predictable conclusions about how organisms behave. The ecclesiastical origins of modern culture and the contemporary social unrest were quoted as causes for the public distrust of the mechanist conception of life, at a time when the materialistic tradition appears to be entrenched in the laboratory more strongly than ever before. Dr. J. H. Woodger (London) went a step further by proposing to apply to the study of biological questions, not only physical methods, but also an appropriate notation of mathematical logic derived from the method of Russell and Whitehead. He was thus led to predict a gradual displacement of the notion of 'stuff' by that of 'system'; so that the notion of 'protoplasm' or 'living matter' would have to go the way of 'hereditary substance', when the scientific worker will learn to think of cells more in term of systems, and less in terms of stuff. A mechanist conception of biology seemed to linger also in the mind of Prof. A. Joffe (Moscow), though he admitted that physicists have to use biological methods for the finest measurements. He quoted the experiments of Prof. Gurtwitsch, who claims to have discovered ' biological rays ', in support of the closer relationship between physics and biology, which will lead in time, he hoped, to the disappearance of the ' mysterious ' vitalistic conceptions.

The fourth section of the Congress, presided over by Sir Henry Lyons, Director of the Science Museum, dealt with "The Interdependence of Pure and Applied Science". Sir Napier Shaw, Prof. C. H. Desch, Prof. F. G. Donnan, Dr. G. Windred, Mr. R. V. Vernon, Dr. Marie Stopes, and Prof. W. Mitkewich illustrated the various aspects of the problem, and seemed to agree that a study of scientific history makes it evident that there can be no independence between pure research and experiment on one hand, and the practical application of scientific principles on the other hand. Further, it appears that the present tendency of intense specialisation makes the progress of science more than ever dependent upon the co-ordination of pure and applied science.

At a meeting of the Committee on July 5, the following were elected members of the International Council for the period 1931–34: Prof. Karl Sudhoff, of Leipzig (*President*); Prof. Gino Loria (Genoa), Dr. Charles Singer (London), Prof. Paul Diepgen (Berlin), Prof. Julian Ribera (Madrid), Prof. George Sarton (Harvard); Mme. Hélène Metzger, of Paris (*Treasurer*), and M. Aldo Mieli, of Paris (*Secretary*). The next Congress will be held in Berlin in 1934.

Such was the general trend of the labours of the Second International Congress of the History of Science and Technology. As Dr. Singer has long been claiming, the history of science can take its place not only among the departments of high scholarship, but also as an integral part of training and discipline in the general study of history. Science cannot assume her just position in education until the educator himself recognises the part that science has taken in shaping the social and intellectual environment in which we live. If the scientific process come to be recognised as a great part of our great inheritance, the Congress will have gone a good way towards achieving its objective. THOMAS GREENWOOD.

The British Australian New Zealand Antarctic Research Expedition.

THE second cruise of the *Discovery*, under the title of the British Australian New Zealand Antarctic Research Expedition, ended on March 27 with the arrival of the ship and party at Melbourne. The health of Sir Douglas Mawson and his men has been excellent, and they have added greatly to our scientific knowledge of the Antarctic continent.

It has been definitely established that the coast-line is continuous through a great arc from Cape Adare to Enderby Land, which is nowhere far removed from the Antarctic Circle. New land totalling 16° of longitude has been discovered, and further detailed charting has been carried out of the 13° discovered on the first cruise last year. The field work extended through one-third of the circuit of the Antarctic region, beginning at the new 180th meridian and ranging west to long. 60° E. Additional features have been added to the coast lines of Adelie Land and Wilkes Land. It has been shown that there is no land in the latitudes assigned for North's Highland, Totten's Highland, or Budd's Land. The name Banzare Land (from the initials of the Expedition's title) has been given to a stretch of territory running from a well-defined cape near the juncture of the 66th parallel and the 127th meridian. It is proposed to maintain the title Sabrina Land for an area observed from the aeroplane between the 115th and 116th meridians at about the 66th parallel. At the end of Wilkes Land is an ice land about 1300 ft. high, which has been charted as Bowman Iceland, in honour of the Director of the American Geological Society. Princess Elizabeth Land is a newly discovered region commencing at the 80th meridian on the 76th parallel and extending south and west in a great sweep to Cape Amery. All the salient features of the MacRobertson Land coast have been charted and named. It is a most interesting region, diversified with mountains, peaks, and islands.

Apart from the geographical work, an immense mass of scientific data has been accumulated by the Expedition. Considerable delineation of the sea floor has been possible with an echo sounder, and many examinations of vertical marine stations were carried out. Daily nettings for marine life and chemical examination of waters have been made, as well as investigations on bacteria in sea water and their rôle as denitrifiers. A two-hourly meteorological record was maintained, and the pilot balloon work was very successful. An interesting fact established is that the violent winds of certain parts of the Antarctic are mainly confined to the surface, seldom extending more than 500 ft. or 1000 ft. above ground-level. Useful observations in magnetics, solar radiation, and cosmic penetration have been made, while, of course, a rich harvest has been reaped in glaciology, geology, and ornithology.

The *Discovery* sailed from Melbourne about the middle of April and, if not delayed, may be expected in London shortly.

A New Heat Engine.

At the Royal Society of Arts on June 4, Mr. J. F. J. Malone, in a paper entitled "A New Prime Mover", gave a description of a form of heat engine, invented by himself, in which the working medium is a liquid instead of a gas. In the course of his paper he stated that though mercury and oil have been tried, water has been found to be the most suitable medium, and in the engines to which reference was made only water has been used.

The main parts of the new form of engine consist of one or more working cylinders, a large number of long thick steel tubes in each of which is a movable displacer or regenerator, and a furnace. The tubes the author calls the thermodynamic tubes or 'T.D. tubes', and the regenerators, the thermodynamic piles or 'T.D. piles'. The tubes are closed at one end and at the other end are connected by pipes to the working cylinders. They are set in groups with their closed ends in the furnace, while the other ends are surrounded by water for cooling. The T.D. piles are built up of thin plates or tubes very closely spaced. The interior of the T.D. tubes, the very narrow spaces in the piles, the connecting pipes, and the working cylinders form a closed system completely full of water, which, when the engine is prepared ready for starting, is under an initial pressure of 1·4 tons per sq. in.

The engine depends for its action on the alternate expansion and contraction of the water in the system, due to the heating and cooling of the water in the T.D. tubes and piles, as the latter are moved to and fro in the tubes. For all practical purposes, the moving of the piles, which is done automatically by the engine, is equivalent to the alternate application and removal of the source of heat. Under these conditions the moving of the piles causes the pressure to rise to about 5·3 tons in one part of the stroke and then to fall to 1·4 tons per sq. in. Much ingenuity has been shown in the construction of the piles, which at first sight might appear likely to give trouble, but which have proved reliable on service.

Unfortunately, though the paper gave a few details of the several engines which have been built and run, these were by no means sufficient to form an estimate of the place the engine is likely to fill. One experimental engine was said to have run over 30,000,000 revolutions, and on three brake tests by three different independent engineers an indicated efficiency of 27 per cent was obtained. It was also stated that allowing for furnace and mechanical losses, it was anticipated with a 100 h.p. engine an over-all efficiency of 20 per cent can be obtained, and this on a weight of about 330 lb. per indicated horse power. In the conclusion of his paper Mr. Malone claimed that the new engine possesses features which make it suitable both for locomotives and for ships.

University and Educational Intelligence.

Birmingham.—The degree of D.Sc. has been awarded to the following: Jonquei Su-Kwang Lee, for published work on "The Fusulinidæ of North China" (*Palæontologia Sinica*, series B, vol. 4), "Some Characteristic Structural Types in Eastern Asia and their Bearing upon the Problem of Continental Movement", "Geology of the Gorge District of the Yang-tse with special Reference to the Development of the Gorge", and other papers; Harry W. Webb, for published work on "Absorption of Nitrous Gases", "Limitation of the Capacity of Platinum Catalyst in Ammonia Oxidation", and other papers.

Dr. A. Stanley Barnes has been appointed Dean of the Faculty of Medicine, in succession to Prof. Brash.

The following appointments have been made: Dr. R. H. Hopkins, lecturer and head of the Department of Brewing in the Heriot-Watt College, Edinburgh, to the Adrian Brown chair of brewing; Mr. R. D. Lockhart, lecturer in anatomy, University of Aberdeen, to the chair of anatomy; Mr. P. Gray and Mr. D. Richards, to be resident staff tutors for adult education under the Joint Committee of the University and the W.E.A.

Prof. A. M. Carr-Saunders has accepted an invitation to hold the Muirhead Lectureship for a further year.

Cambridge.—The Harkness scholarship for proficiency in geology, of value £117, has been awarded to Miss F. E. S. Caldwell, of Newnham College.

The Frank Smart prizes have been awarded to P. W. Richards, of Trinity College, for botany, and P. Ullyett, of Trinity College, for zoology.

Edinburgh.—At the graduation ceremony on July 2 the honorary degree of doctor of laws was conferred on the following, among others: Dr. E. J. Allen, Director of the Marine Biological Laboratory, Plymouth; Sir George Andreas Berry, M.P. for the Scottish Universities, formerly lecturer in ophthalmology in the University of Edinburgh; and Sir Walter Morley Fletcher, secretary of the Medical Research Council.

The degree of doctor of science was conferred on Lucy Boyd, for a thesis on "Studies in the Post-Seminal Development of the Monocotyledonous Embryo"; A. Cunningham, for a thesis on "Studies on Soil Micro-Organisms"; Esmé Mary Gilroy, for a thesis on "The Influence of Arginine upon Growth and Tissue Repair"; Dr. M. Young, for a thesis on "A Contribution to the Study of the Growth of the Face in Childhood".

Leeds.—At a graduation ceremony in connexion with the hundredth anniversary of the Leeds School of Medicine, the following honorary degrees were conferred, among others: Degree of doctor of laws—Prof. A. G. Barrs, emeritus professor of medicine at Leeds and for more than fifty years connected with the School of Medicine; Sir John Bland-Sutton, consulting surgeon at the Middlesex Hospital; Lord Dawson of Penn, president of the Royal College of Physicians; and Sir George Newman, Chief Medical Officer, Ministry of Health. Degree of doctor of science—Sir Walter Morley Fletcher, secretary of the Medical Research Council; and Sir Frederick Gowland Hopkins, president of the Royal Society

London.—The late Mr. J. F. H. Knight has bequeathed to the University a moiety of his residuary estate for the furtherance of teaching and research in the University. The bequest is expected to amount to about £25,000.

NOTTINGHAM.—Dr. Henry L. Brose, at present reader in atomic physics, formerly Rhodes Scholar at Christ Church, Oxford, has been appointed to the chair of physics, which is about to become vacant owing to the retirement of Prof. P. E. Shaw.

ST. ANDREWS.—At a meeting of the University Court on June 23, Dr. F. L. Arnot, of Trinity College, Cambridge, was appointed lecturer in natural philosophy in the United College, St. Andrews, as from Oct. 1. Dr. George L. Montgomery was appointed lecturer in clinical pathology in the University.

The Court confirmed the acceptance of contracts for the erection of a new building for the botany and geology departments, a new lecture theatre for the zoology department, and a new laboratory for the anatomy department, to form part of the group of Bute Medical and Bell-Pettigrew Museum Buildings at St. Andrews.

DR. J. D. STIRLING has recently been appointed to the staff of the Hannah Dairy Research Institute, Kirkhill, Auchincruive, Ayr. For the past three years Dr. Stirling has been doing research work in biochemistry at the University of Glasgow under the direction of Prof. E. P. Cathcart, and later at Tübingen in Germany and Graz in Austria.

THE second year's awards of the Sir James Caird Travelling Scholarships have recently been announced. The scholarships were instituted by the will of the late Mrs. Emma Grace Marryat, who was a sister of the late Sir James Caird, Bart., of Dundee. A sum of £200,000 was appointed to be held in trust for the foundation of the scholarships in engineering, electricity, aeronautics, and music. Only natives of Scotland, of either sex, who are not already holders of scholarships similar in nature to those offered, are eligible for these scholarships. Two classes, junior and senior, are offered. The value of the junior varies from £50 to £150 and the senior from £250 to £600 per annum. Each scholarship is tenable for one year; but may be extended yearly to a maximum of three years. Among the scholarships awarded for this year were the following: Engineering (junior of the maximum of £150), T. C. Inglis, W. A. Sangster; (senior of the normal amount of £400), J. Jamieson. Electricity (junior of the maximum of £150), J. C. M. Sanders, H. C. Thompson; (senior of the normal amount of £400), M. D. Kippen, J. M. Dodds. Aeronautics (senior scholarship of £300), J. A. J. Bennet.

THE Medical Research Council has made the ollowing awards of travelling Fellowships for the academic year 1931–32 on behalf of the Rockefeller Foundation: Mr. E. T. Conybeare, Guy's Hospital, London; Mr. G. M. Dean, Department of Surgery, University of Aberdeen; Mr. M. H. Finkelstein, Department of Bacteriology, University of Edinburgh; Prof. O. S. Gibbs, formerly professor of pharmacology, Dalhousie University, Canada; Mr. E. M. Lourie, Liverpool School of Tropical Medicine; Mr. A. W. Spence, St. Bartholomew's Hospital, London; Mr. C. H. Waddington, Strangeways Research Laboratory, Cambridge; M. K. H. Watkins, Royal Infirmary, Manchester. The Fellowships awarded to Prof. Gibbs and Mr. Waddington are tenable in Europe, the others at centres in the United States. These Fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a chosen centre in the United States or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles.

Societies and Academies.

EDINBURGH.

Royal Society, June 15.—A. H. Reginald Buller: (An address) Recent advances in our knowledge of the higher fungi. A mushroom is the reproductive part of the mushroom plant and is produced at the expense of the mycelium or spawn. A large mushroom may develop and liberate upwards of 10,000,000,000 spores. The basidiospores of all Hymenomycetes, all Uredineæ, the smut-genus *Tilletia*, and the yeast-genus *Sporobolomyces* are shot away by a drop-excretion mechanism, but exactly how this mechanism works is still a profound mystery. The terminal rate of fall of spores in still air varies with the size of the spores from about 0·5 to 4·0 mm. per sec. Spores are discharged from the under side of the caps of mushrooms and toadstools in a continuous stream for days or weeks. The clouds of spores escaping from a fruit-body can be made visible in a darkened room by means of a beam of light. Nocturnal excursions with an electric lamp may be made to observe spore-discharge from fruit-bodies attached to tree-trunks, etc. The organisation of the hymenium which covers the gills of mushrooms and toadstools has been worked out, and the time and space relations of the basidia which produce the spores and of the sterile elements called paraphyses are now known. The basidia come to maturity in a series of successive generations. The sexual process in mushrooms and toadstools is initiated in the mycelium with nuclear association, is continued there with conjugate nuclear divisions, and is completed in the fruit-body by nuclear fusion in every basidium.—**J. Thomson**: The ionising efficiency of electronic impacts in air: Experiments are described, the aim of which is the determination of the average energy required to produce one pair of ions in air by electronic impact, the initial energy of the electron being defined. The results show that the total number of ions produced is a linear function of the initial electronic energy. Hence it is shown by extrapolation that for fast-moving electrons (such as β-rays) the energy per ion-pair is 37 ± 2 electron-volts. This result is discussed in relation to other investigations, and the extrapolation is thereby justified.

PARIS.

Academy of Sciences, May 18.—A. Lacroix: The nepheline and leucite phonolites of the island of Ua-Pou (Marquesas Archipelago).—**A. Cotton**: Comparison of the magnetic rotations of crystallised quartz and fused quartz. The specific magnetic rotation of fused quartz was found to be greater than that of crystallised quartz.—**L. Cayeux**: The petrographic characters of the magnesian irregularities in the chalk of the Paris basin.—**Charles Richet**: The reflexes of acquisition (Pavloff's conditional reflexes). A claim for priority as regards the work of Pavloff.—**Charles Nicolle and Ugo Lumbroso**: The *Bacterium granulosa* of Noguchi in its relations with the etiology of trachoma. Two strains of this bacillus (Noguchi, Olitski) proved to be devoid of pathogenic power. It is mentioned as possible that there might have been an attenuation of the virulence due to the age of the culture.—**S. Finikoff**: Congruences of which the two sheets of the focal surface are projectively applicable one on the other by the corresponding focal points.—**Marcel Vasseur**: A geometrical interpretation of Moutard's transformation.—**J. Leray**: A system of partial differential equations which governs the permanent flow of viscous fluids.—**Mlle. Nina Bary**: The representation of continued functions by means of functions with limited variation.—**R. Gosse**: The investigation of a category of equations of the first class.—**Stefan Kempisty**: The integral (A) of Denjoy.—**A. Rauch**: The generalisation of theorems of Valiron on meromorph functions of positive order.—**Jean Brille**: A property of functions presenting a certain complex character of resolvability.—**F. E. Myard**: Closed chains with four rotoid non-concurrent couples, deformable at the first degree of freedom. Toric isogram.—**Henri Poncin**: Cavitations (in fluids) of permanent form.—**A. Lafay**: The deviations of the push of the wind on a cylinder produced by very small superficial projections on the latter.—**Mme. G. Camille Flammarion**: Photographs of the planet Mercury. A detailed description of the markings observed is given, with a drawing. It is the first time that details of the surface of this planet have been obtained by photography.—**Ž. Horák**: The space-time line of a material point in classical mechanics.—**G. Ribaud**: The distribution of the temperatures in the cross-section of a flat incandescent filament.—**R. Jouaust and N. Stoyko**: The propagation of short radio-electric waves. For some time in 1930 and 1931 radiotelegraphic transmissions on 18·5-metre waves between Indo-China and France were bad; for each signal sent more than one was received. The difference of time between the two signals received has been measured on a Blondel oscillograph and found to be 0·0681 second. In the light of this figure, two hypotheses regarding the paths of the waves are discussed.—**P. David**: A valve generator with very stable frequency. Instead of controlling the frequency of an emitting valve with a quartz oscillator or tuning fork, the author proposes the use of a valve with two grids, and describes the arrangement of the circuit found to be most suitable. For variations in the voltages of 15 per cent the variations in the frequency do not exceed five millionths.—**F. Esclangon**. The theory of the discharge without electrodes. According to the theory of Sir J. J. Thomson, the electrodeless discharge in a rarefied gas placed inside a solenoid carrying a high-frequency current is to be attributed to the electric field induced by the alternating magnetic field of the solenoid. Townsend and Donaldson showed that the electrostatic changes on the turns of the solenoid produce an additional and more intense field. Experiments are described by the author by which these two effects can be separated.—**Mlle. Paule Collet and G. Foex**: The influence of the field on the magnetic states of platinum. In these experiments the magnetic fields varied from 14,000 gauss to less than 3000 gauss, and the temperature from − 180° C. to 200° or 400° C. The results are summarised in two diagrams.—**P. Lainé**: The errors introduced by inexactitude of the half-wave plates in the analysis of slightly elliptical vibrations, and on the standardisation of half-wave and quarter-wave plates.—**C. Salceanu**: The natural and magnetic rotary polarisation of some organic compounds studied in the liquid state. Wiedemann's rule, that the ratio of the magnetic to the natural rotation is independent of the wave-length, holds for menthol, but not for fused camphor or carvone.—**S. Takvorian**: Investigation on element 61 by means of the X-rays. Starting with 14 kilograms of cerium earths, after a preliminary treatment increasing the proportions of neodymium and samarium oxides, the method of fractional crystallisation of the double magnesium nitrates was used. The fractions examined, which were those in which element 61 ought to be concentrated, and which only represented 1/200th of the weight of the initial oxides, gave no evidence of the presence of element 61, at least in a proportion higher than 1 in 10,000.—**M. Schérer**: The magnetic double refraction of liquid hydrocarbons.—**A. Sanfourche**: The electrometric titration of phosphoric acid. The results obtained with hydrogen and quinhydrone electrodes using soda, lime, strontia, and baryta as alkalis are shown graphically.—**Mlles. C. Chamié and A. Korvezee**: The centrifugation of solutions of polonium in the presence of various electrolytes. A solution of polonium, filtered before the experiment, gives a precipitation of 40 per cent of the polonium. This proportion is increased by the addition of electrolytes ranging from 50 per cent for sodium nitrate to 99·6 for silver nitrate.—**H. Colin and Mlle. A. Chaudun**: The hydrolysis of sugar by strong acids in the presence of their salts.—**Barbière and Desmaroux**: The solvent power of the alcohols for the nitrocelluloses.—**F. Bourion and Mlle. O. Hun-**: The boiling point determination of the molecular equilibria of pyrocatechol in lithium chloride solutions.—**A. Damiens**: A new porcelain without silica, based on pure fluorspar. Starting with mixtures of finely divided fluorspar and precipitated calcium fluoride, it has been found possible to prepare a material resembling porcelain, and which is unattacked by fluorine or by hydrofluoric acid.—**G. Arrivaut**: The action of arsenic chloride upon nickel. The first product of the reaction between finely divided nickel and an acid solution of arsenious chloride was the compound Ni_3As_2.—**J. Bougault and G. Schuster**: A new triglyceride obtained from cocoa butter: a palmitostearoazelain.—**Tseou Héou-Féo**: The condensation of an amine and of formaldehyde with quinaldine and picoline.—**J. Wyart**: Study of chabase.—**A. Rivière**: Remarks on the stratigraphy of the base of the Eocene in central Elbourz.—**Jean Lacoste**: Tectonic observations on the southern Rif (Moulay Bou Chta region).—**Joseph Blayac and Marcel Thoral**: The discovery of Georgian Trilobites in the Montagne Noire (Hérault).—**J. Thoulet**: Deep submarine volcanoes.—**H. Arsandaux**: The morphological evolution of the dome of Montagne Pelée.—**F. Roman and J. Dareste de la Chavanne**: The presence of an elk (*Alces latifrons*) in the upper Pliocene of Senèze (Haute-Loire).—**A. Duparque**: The microscopic structure and origin of anthracite.—**Alfred Carpentier**: Some imprints of seeds of Pteridosperms.—**Mlle. G. Py**: The evolution of the cytoplasmic constituents of the nutritive layer of the pollen in *Vincetoxicum officinale*.—**A. Guillaumin**: The transformation of the lower portion of the axis of inflorescence into a hook in the Uncaria.—**Paul Becquerel**: The development of the male fern in a pure aseptic culture starting from the spore.—**J. Chaze**: Experimental proofs of the excretion of nicotine from the aerial parts of the tobacco plant. A direct proof is given that nicotine is excreted by the tobacco plant and evaporated into the surrounding air.—**M. Bridel and C. Charaux**: The purgative complex of elder buckthorn bark, soluble in water and hydrolysable by rhamnodiastase.—**Henri Perrin**: Indices of aridity and types of forest vegetation.—**Charles Pérez**: Statistics of infestation of hermit crabs by *Chorogaster*.—**Mme. Lucie Randoin and Mlle. Andrée Michaux**: Variations in the proportion of globulin and serum in blood serum under the influence of a diet thrown out of equilibrium by the complete absence of antiscorbutic vitamine.—**J. Vellard**: Poison of the ray (*Tœniura*) from the Rio Araguaya (Brazil).—**Emile Haas**: The extent to which the central visual acuteness is altered when a very bright object is near the test to be defined. A study of the effects of dazzle.—**A. Leulier and B. Drevon**: Action of the blood on morphine chlorhydrate.—**H. Bierry**: Specificity and chemical structure.—**Bunzô Hayata**: The dynamic system of plants based on the theory of participation.—**J. Laurin**: The hypoglycæmic action of the bulbs of *Allium cepa*.—**Raymond-Hamet**: The mechanism of the action of the sympathomimetic amines.

Geneva.

Society of Physics and Natural History, Feb. 19.—**G. Dejardin**: (1) The utilisation of ultra-violet light in photoelectric cells with glass bulbs. The author exhibits photoelectric cells in which the quartz, as transparent material, is replaced by an extremely thin glass window (some hundredths of a millimetre). For ordinary cells, without the thin wall, the spectrum range can be extended considerably by depositing on the window a thin layer of a fluorescent substance such as mineral oil, vaseline, or esculin incorporated in gelatine.—(2) The extension of the spectrum sensibility of photoelectric cells under the action of oxygen. The spectrum sensibility of very thin films of the alkali metals increases considerably when the surface of the metal serving as the support (copper, silver, magnesium) is oxidised. In the case of potassium, the presence of the oxygen produces a displacement of the whole spectrum towards the red of the sensibility curve. The author shows that by this method films can be obtained with potassium which can in many cases replace those of cæsium.—**E. Briner** and **B. Susz**: The maximum concentration of endothermic compounds at high temperatures (calculated in collaboration with E. Rod). Following on earlier researches, the authors establish by calculation the existence of a maximum concentration for endothermic compounds such as ozone and nitric oxide. For ozone the maximum concentration is very low. For nitric oxide it amounts to 3·6 per cent at 4000° Abs. in an equimolecular mixture of nitrogen and oxygen at atmospheric pressure.—**P. Balavoine**: The analytical characters of caramel regarded as a colouring matter for food. A close study of certain analytical characters of this colouring matter compared with artificial colouring matters. A new reaction is described suitable for detecting caramel in the presence of other natural colouring matters.—**G. Ladame**: The central Rhodopes and the Balkans. Geological and mining outline. After some brief geological data based on the work of Stephan Bončev, the author gives five analyses of selected specimens of sulphide ores of zinc, lead, and copper, the latter containing more or less silver. Fairly numerous researches have not resulted in extensive mining operations. There are important deposits of tertiary lignites, and mining for these is more probable.

Washington, D.C.

National Academy of Sciences (*Proc.*, Vol. 17, No. 1, Jan. 15).—**Matilda Moldenhauer Brooks**: The penetration of 1-naphthol-2-sulphonate indophenol, *o*-chloro phenol indophenol, and *o*-cresol indophenol into *Valonia*. As with indigo sulphonates, the first does not penetrate into the sap, suggesting that the sulphonate radicle is responsible. The other dyes penetrate in a colourless form.—**Henry Borsook** and **Howard M. Winegarden**: (1) The work of the kidney in the production of urine. The minimum work performed by the kidney in man in the production of urine, analysed by the second law of thermodynamics, is of the order of 0·7 gm. cal. per c.c. of urine or 70 gm. cal. per gm. of nitrogen excreted.—(2) The energy cost of the excretion of urine. Production of hyper- or hypotonic urine entails work by the kidney. The energy consumed by the normal healthy kidney in man is 6-11 kgm. cal. per gm. nitrogen excreted, an efficiency of only 1-2 per cent. The healthy kidney has a great capacity for work, which is much reduced by disease, drugs, etc. The paper contains an extensive review of work on the subject.—**J. H. Hodges** and **E. F. Linhorst**: The thermal decomposition of nitrogen pentoxide. At 35° C., the reaction appears to be unimolecular at partial pressures of 0·12 mm. to 0·06 mm.; below 0·06 mm. pressure, specific reaction rate decreases with pressure, and below 0·004 mm. pressure it appears to be bimolecular.—**Oscar Knefler Rice**: On the transfer of energy between atoms at collision. A theoretical discussion. A modification of Born's method is outlined, taking into account the mutual kinetic energy of the particles. The method gives an upper limit to the radius of action.—**G. A. Miller**: Groups which admit five-eighths automorphisms.—**M. S. Knebelman**: Multivectorial curvature.—**Tracy Yerkes Thomas**: On the unified field theory (3). A general existence theorem is derived and the characteristic surfaces of the four-dimensional world are determined.—**E. H. Kennard**: Quantum mechanical motion of free electrons in electromagnetic fields. Formulæ are obtained by Ehrenfest's method for the motion of the centroid of a wave-packet; only the non-relativistic case is considered, based on Schrodinger's equation. The general result is that in a uniform electric or magnetic field the packet-centroid moves as an electron should according to classical theory, and in non-uniform fields its acceleration is a kind of average of the classical value.—**Carl Størmer**: Remarks on a paper: Note on the nature of cosmic rays, by Paul S. Epstein. The results for the motion of electrons in the field of an elementary magnet obtained by Epstein (*Proc. Nat. Acad. Sci.*, Oct. 1930) were derived by Størmer in 1904.—**Ernest O. Lawrence** and **David H. Sloan**: The production of high-speed canal rays without the use of high voltages. A series of metal tubes in line are attached alternately to the inductance of a high frequency oscillatory circuit. An ion between the first and second tubes is accelerated into the second tube, and if the length of this tube is such that the time taken to pass through it is equal to the half-period of the oscillator, the ion will be further accelerated into the third tube and so on. An apparatus containing twenty-one accelerators has been made and with it mercury ions of kinetic energies of more than 200,000 volts have been obtained with a maximum applied voltage of about 10,000 volts. The method is capable of further development.—**G. Breit**: On the interpretation of Dirac's α-matrices.

Official Publications Received.

TUESDAY, July 14.

Quekett Microscopical Club (at 11 Chandos Street, W.1), at 7.

THURSDAY, July 16

Genetical Society (at Entomological Society of London, 41 Queen's Gate, S.W.7), at 3.—Exhibits and Demonstrations by Prof. E. B. Poulton, Dr. A. D. Imms, J. C. F. Fryer, and others.—At 5.—Annual General Meeting.

National Smoke Abatement Society (at 71 Eccleston Square, S.W.1), at 3.15.—W. Prescott: Smoke Abatement from the Manufacturers' Point of View (Address).

CONGRESSES.

July 6 to 11 (in Edinburgh).

Congress of Universities of the Empire.

Friday, July 10, at 10.30 a.m.—Address by Sir Donald Macalister, Bart.
At 11 a.m.—Dr. H. L. Eason and others: Discussion on Post-graduate Study in Medicine and Surgery in Great Britain.
Sir Thomas H. Holland and others: Discussion on Facilities for Overseas Students in British Universities.

Saturday, July 11.—Visits.

July 9 and 10.

Ophthalmological Congress (at Oxford).

Friday, June 10.—Dr. Baillart: Tonometry.
P Adams: An Ophthalmological Mélange (Doyne Memorial Lecture).
J. Craig and Prof. Schuller: Discussion on Penetrating Wounds of the Eye.

July 10 and 11.

Society for Experimental Biology (at Rothamsted Experimental Station, Harpenden).

Friday, July 10 (In Chair: Dr. W. B. Brierley).
At 11.30 a.m.—W. H. Pearsall: The Effects of Calcium on the Metabolism of *Chlorella*.
J. H. Priestley: Growth as a Factor in Food-transport in Plants.
M. A. H. Tincker: Some Factors Affecting Tuber Formation.
At 2.—Address by Sir John Russell.
At 5 (In Chair: Dr. A. D Imms).—V. B. Wigglesworth: The Physiology of Excretion in a Blood-sucking Insect, *Rhodnius prolixus*.
R. P. Hobson. Digestion in Blow-fly Larvæ.
At 6.—Business Meeting.

Saturday, July 11 (In Chair: Dr. D. Ward Cutler).
At 10.30 a.m.—N. N. Murti: The Artificial Production of Double-pored Larvæ in *Asterias glacialis*
S. Zuckerman: The Reproductive Mechanism in Primates.
J. S. Huxley: Recent Work on Differential Growth.
Boris Zavadovsky: Research Work at the Institute of Neuro-humeral Physiology, Moscow.
A. T. Yoffe. Recent Work on Mitogenetic Rays.

July 13 and 14.

International Union for Biological Sciences (at Brussels).

July 20 to 23.

British Pharmaceutical Conference (at Manchester)

Monday, July 20, at 8 p.m.—Civic Reception by the Lord Mayor and Corporation.

Tuesday, July 21, at 10 a.m.—Chairman's Address.
At 11.15 a.m. and 2.15 p.m.—Science Meetings.
At 2.15 p.m.—Delegates' Meeting.

Wednesday, July 22, at 10 a.m. and 2 p.m.—Science Meetings.
At 10 a.m.—Delegates' Meeting

Thursday, July 23, at 10 a.m.—Closing Session.

JUBILEE CELEBRATION AND ANNUAL MEETING.

July 13 to 19.

Society of Chemical Industry (in London).

Monday, July 13 (at Central Hall, Westminster), at 11.30 a.m.—Opening of Chemical Plant and Research Instruments Exhibition.

Tuesday, July 14 (at Royal Academy of Music), at 10 30 a.m.—Annual General Meeting.
Sir Harry McGowan: Presidential Address.
(At Salters' Hall, St. Swithin's Lane), at 7 p.m.—Dr. G. Engi: Recent Developments of the Society of Chemical Industry in Basle.
Dr. H. Schicht: Address.
(At Home Office Industrial Museum, Horseferry Road), at 9 p.m—Prof. R. V. Wheeler: Dust Explosions.

Wednesday, July 15 (at Royal Academy of Music), at 10.30 a.m.—Presentation of Society's Medal to Dr. H. Levinstein and Address by the Medallist.

Thursday, July 16 (at Leathersellers' Hall, St Helen's Place), at 10.30 a.m.—Dr. H. Sorensen: Hydrogen Ion Concentration
(At Great Central Hotel), at 10.30 a.m.—Reading and Discussion of Papers.

Friday, Saturday, and *Sunday, July* 17, 18, and 19.—Visits.

SUMMER MEETINGS.

July 13 to 17.

Institution of Mechanical Engineers (at Cambridge)

Tuesday, July 14, at 10 30 a.m.—Prof. C. E. Inglis: Cambridge as a Place of Education (Address).
At 11 a.m.—H. N. Gresley: Locomotive Experimental Stations.

Wednesday, Thursday, and *Friday, July* 15, 16, and 17.—Visits.

July 18 to 23.

Institution of Electrical Engineers (in Northern Italy and Western Switzerland).

Against Foreign Pests.

THE history of agricultural pests suggests that there is a strong tendency for any creature imported from a foreign country, so long as conditions of food and climate favour its survival, to outrival native pests and to become a real burden in the land of its adoption. So often has this happened that many nations have taken the warning to heart and have adopted laws forbidding, without permit from the proper authorities, the importation of foreign creatures. Great Britain, always a little slow in admitting that science can teach it, has been content to place a ban upon certain insect pests which are liable to come unawares with food materials or other vegetation, but has made no provision against the open and deliberate importation of animals which harbour the possibility of much damage.

Such is the case of the musk-rat or musquash, to the importation and breeding of which in Scotland, for the sake of its fur, attention has already been directed in these pages. Indeed, we believe that the appearance of several notes in NATURE discussing the inordinate spread and the damage caused by the musk-rat in central and southern Europe, led to the investigation which has resulted in the first attempt in Great Britain to control the importation of the larger potential pests.

The musk-rat (*Fiber zibethicus* or *Ondatra zibethica*) is an American rodent somewhat resembling a small beaver, which, imported to Europe to be bred for its fur, has within the last twenty years spread enormously along the valley of the Upper Danube and has penetrated and colonised adjacent river systems, causing damage to flood-embankments and river-banks by burrowing, and to agricultural produce, especially green crops and roots. Bavaria and other States employ men trained and specially detailed to trap musquash, and in Bavaria alone as many as 33,000 have been destroyed in a year. Much controversy has arisen in Europe concerning the need or otherwise of prohibiting the musk-rat from countries yet free from its presence; for although central Europe has suffered heavily and has made many unsuccessful attempts to rid itself of the pest, in other parts—Finland is an example—breeding has been carried on successfully without, it is said, any untoward results. The difference seems to depend upon modifications in the rate of breeding and increase of numbers due to climatic differences; but it cannot be forgotten that success in the breeding of fur animals depends upon rapid multiplication, and that the very countries which claim the musk-rat to be harmless are by that indicating that its commercial exploitation there is less likely to be an outstanding success.

In Scotland, musquash were imported for breeding purposes only in 1927, and at first all were bred in captivity. But by accident or otherwise various pairs have escaped, so that in three areas they are known to be at large, and in one Scottish district in 1929 as many as sixteen musquash 'huts' were seen at a time, an indication that conditions there seemed to favour that rapid multiplication of the animal which leads to plague conditions.

A few months ago, the Ministry of Agriculture and Fisheries, following upon an investigation made regarding the presence of musk-rats in wild conditions in Scotland, issued a notice requesting any person keeping and breeding musk-rats to inform the Ministry of the fact and of the number of the animals. Speedy action has followed the issue of that notice, for the Parliamentary Secretary to the Ministry, Earl de la Warr, has now introduced a "Destructive Foreign Animals Bill" to the House of Lords, where it was given a first reading. The text of the Bill, issued on June 24, indicates that power would be given to the Minister of Agriculture and the Secretary of State for Scotland, acting jointly, to prohibit by order, either absolutely or except under a licence, the importation into and the keeping within Great Britain of any animal of the species.

The occupier of any land who knows that musk-rats not kept by him under licence are to be found upon it, is required to give notice to the appropriate department, which may take all the steps necessary for their destruction. Anyone importing or attempting to import musk-rats without a licence at a time when this is prohibited, or failing to comply with the terms of his licence, or who turns loose or wilfully allows a musk-rat to escape, would be liable to various penalties. On the other hand, compensation would be paid to persons keeping musk-rats for profit in respect of loss caused by their being compelled to destroy the animals under an order. Special licences may be granted to persons wishing to keep musk-rats for exhibition or scientific research; but the granting of such special licences would have to be accompanied by special precautions, since musk-rats kept for exhibition or research which have escaped, are just as dangerous fellows as escapes from breeding-pens.

The Bill contains a section which adds enormously to its significance: power is given to extend its provisions to other destructive animals "of any foreign mammalian species".

We trust that this Bill, to which the House of Lords has granted a first reading, will make rapid progress through both Houses. Whether the musk-rat would ever become such a plague in Great Britain as the alien rabbit has turned out to be, none can tell; but where there is so great a risk it is wise to err on the safe side. Moreover, we should be but following the examples of Norway and Germany, both of which have deemed it necessary to prohibit the importation of this foreign pest.

As an Act, the new measure would signify an important progressive step in the laws relating to animals in Great Britain—a tardy recognition of the fact, from which we as well as other nations are suffering, that more may be involved in the thoughtless importation of strange animals than the importer can possibly conceive.

Anthropology and Native Administration.

IN a review entitled "The Anthropology of Africa" in NATURE of May 2, p. 655, Prof. B. Malinowski pleaded for a fuller acknowledgment of the science of man as a force in colonial affairs, as well as for its academic recognition in the more important universities of Great Britain. The subject, as a matter of fact, is only taught at three universities—Oxford, Cambridge, and London—and neither of the older universities has an established chair of anthropology, in spite of the glorious tradition of Tylor at Oxford and of Haddon and Rivers at Cambridge. The present organisation of the anthropological departments, with such teachers as Dr. R. R. Marett, Mr. Henry Balfour, and Mr. Dudley Buxton at Oxford and Col. T. C. Hodson at Cambridge, would well warrant a full chair at each university.

We are informed that at Oxford the amount of teaching in social anthropology exceeds the twenty hours mentioned by Prof. Malinowski. The course includes lectures in social anthropology by the Rector of Exeter (Dr. Marett), in colonial history by Prof. Coupland, in African economics by Mr. Henry Balfour, and in racial problems by Mr. Buxton—all subjects which come within the range of anthropological studies.

Col. Hodson writes that, so far as Cambridge is concerned, "Prof. Malinowski's statement that the

Colonial Probationers receive only twenty hours' tuition and that anthropology is not obligatory, needs correction. They receive forty hours' tuition, given by lecturers who have African administrative experience, and they are required to attend these lectures. It is hoped to increase and improve this in the immediate future."

These additional facts give further support to Prof. Malinowski's argument in favour of a general strengthening of anthropology in all the universities of Great Britain and of a greater interest being paid to it by administrative authorities. The difference between twenty, thirty, or even forty hours is not material. It is universally acknowledged that anthropology is necessary, and it is not a contentious point that two or even three score hours will remain a superficial smattering. On the other hand, it seems better that specialising should not begin so early as it does on the Continent, and that young men should take up a colonial career only after they have gone through the ordinary university course; and after this they cannot be asked to spend some five more years on a special colonial course.

There is one practicable method of getting over this difficulty which has already in part been adopted by the colonial authorities, and is receiving the serious consideration of the International Institute of African Languages and Cultures, which has its main seat in London. This is, that officers with a special interest in the application of anthropology to problems of native administration should be given study leave after their first or second term abroad. This involves the creation of refresher courses, and private tuition can be arranged at any of the three universities. Colonial Governments have been working on this system, though only to a limited extent, for some years, and it has given excellent results; it might well be more fully developed. It is important that all the universities where teaching in the subject is given should cooperate in the organising of such teaching and that here the University of London should not be passed over.

The combination of a brief anthropological training, such as is now given at Oxford and Cambridge, with refresher courses of a fuller nature, would provide a solution to a problem which becomes more and more urgent in colonial administration, namely, the problem of not over-burdening the young man eager to go out to the Colonies, and yet making it possible for him to gain, later on, the theoretical knowledge which is admittedly essential to his work.

African Settlement and the Origin of Rift Valleys.

(1) *Africa View.* By Julian Huxley. Pp. viii + 455 + 32 plates. (London: Chatto and Windus, 1931.) 15*s.* net.

(2) *Living Africa: a Geologist's Wanderings through the Rift Valleys.* By Bailey Willis. Pp. xv + 320 + 21 plates. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 20*s.* net.

THESE two books have much in common. They state the impressions formed during tours in East Africa by two highly trained scientific observers. The first is by a brilliant British biologist; the other by one of the most distinguished American geologists. Both authors have the philosopher's respect for first principles, high literary skill, keen insight on a wide range of subjects, and a sympathy which enables them to come to a friendly understanding with all sorts of men. Prof. Bailey Willis during an eight months' tour through East Africa travelled 8000 miles, from Pretoria to Baringo, through Rhodesia, Tanganyika Territory, Uganda, and Kenya, and down the Nile, to study the nature and origin of rift valleys. Prof. Julian Huxley's tour of four months in Tanganyika Territory, Uganda, and Kenya Colony was made on the invitation of a Colonial Office Committee to advise on native education.

Both books are highly complimentary to British administration; and the repeated testimony to its efficiency is especially gratifying from the American author, for he can be a candid critic, for example, upon the inferiority of the motor car that he used to its American equivalent. Both authors have returned deeply impressed by the superiority of indirect rule, as shown by the comparison between the results in Tanganyika Territory and in Kenya Colony; and the testimony of two such competent and different observers should be of special value at a time when the issues are being considered by the Joint Committee on East Africa of the two Houses of Parliament. Prof. Bailey Willis quotes with approval the passage in the Duke of Devonshire's dispatch of 1923 which introduced the phrase "the paramountcy of native interests".

(1) The larger part of Prof. Huxley's book is a lucid and suggestive discussion of the fundamental principles of East African administration. He is a warm champion of the system developed by Lord Lugard in Nigeria, which has been applied by Sir Donald Cameron in Tanganyika Territory and

by Sir William Gowers in Uganda, but is opposed by the Settlers' Association in Kenya Colony. The section of "Africa View" that carries most weight is that on education, on which Prof. Huxley writes with expert authority. He regards education as "the great adventure" and the most important and influential of all branches of public service in Africa. He visited many schools and all the chief educational institutions, including Amani, the biological research station, which has been re-established and is now under the directorship of Dr. Nowell. The position of Amani he regards as highly inconvenient, but he deprecates the current criticism that it has not yet been of help to East African agriculture and should therefore either be reduced or discontinued. He thinks that it should be left at work for five years and overhauled then if it has not begun to justify its existence. Both authors visited Mr. Swynnerton and are eulogistic of his anti-tsetse fly researches.

The question of education involves the problem of the missionaries, with whom Prof. Huxley is, in general, sympathetic. He recognises that they are the one section of the European population which is concerned primarily with the welfare of the natives and are therefore an invaluable check on any settlers who may look on the natives as mere 'labour-fodder'. He recognises that the position of the missionaries is strong owing to the generous financial and public support given to them from Europe, and that they represent a 'third estate' in the local realm. He deplores, however, the narrow outlook of some of them and suggests, in view of their political influence and the mischief done by some, that no missionary should be admitted without a sound training in social anthropology. The missions are especially important for their share in education; but some of the mission schools are so defective that he estimates that "only 30 to 40 per cent of the children put down as attending mission schools in East Africa were getting an education worth calling an education". Missionary co-operation in education there is indispensable, but needs control. The Colonial Office Education Committee for East Africa was established with an unduly high clerical bias. Prof. Huxley is emphatic that the natives must be allowed an education of which the basis is a knowledge of reading and writing; for the core of African primary education he recommends biology and geography. On the controverted issue of the language to be used in the schools, he adopts the conclusion, which Indian experience suggests as sound, that the elementary teaching should be in the local vernacular, followed by use of a lingua franca in the higher classes: the second language at present used is Suahili. Prof. Huxley regards that choice as justified in present circumstances; but he is anxious that it should not be permanently engrafted on to the system, and that it should be declared from the outset that English is to be adopted as the second language and Suahili either ousted or reduced to a very secondary position as soon as adequate teachers in English are available.

Prof. Huxley holds that the African can profit by ordinary education. He repudiates the assumption that the Negro is mentally much below the European. He rejects the helpless orphan conception of the Negro and all the policies based on it. He is prepared to believe that the races of Africa are "slightly below the races of Europe in pure intelligence and probably certain other important qualities"; but he is "perfectly certain" that, if so, the difference between the racial averages is small and that the great majority of Negroes and Europeans "overlap as regards their innate intellectual capacities". He is opposed to the implications of the report by the American Phelps-Stokes Commission on African education, which laid great stress on "community adaptation" and approved the settler policy that the education adopted should be designed to fit the natives for their subordinate status, and, as Prof. Huxley puts it, "in fact, to increase their docility and their output in the God-appointed *status quo*".

Prof. Huxley, though warm in his praise of many of the settlers, represents others as reactionary and as anxious to maintain a relation between Negroes and Europeans which is shown by the experience of West Africa and India to be obsolete and impracticable. He devotes one chapter to a criticism of the policy advocated in General Smuts's Rhodes Lectures, which, however, represent a compromise between the two extreme views. For General Smuts upholds the principle that the interests of natives must come first; he favours the segregation of the two races, the whites being given preference in the highlands and the natives in the lower land, the political independence of the native areas under a High Commissioner, and the appointment of an advisory council to act as intermediary between the East African Government and the Colonial Office.

(2) The most important section of Prof. Bailey Willis's book, which happens to be the least satisfactory in Prof. Huxley's, is his consideration of the nature of rift valleys. The investigation of that

problem was the purpose of Prof. Willis's journey and his results will be published in a future monograph, which will be of high value, as it will deal with the question more fully than any previous work on the subject. The main object of the writer's contributions was to establish the tectonic origin of the valleys, the possibility of which was denied by some British geologists. Their tectonic nature being now accepted, the exact mode of their formation is their main problem of current interest.

Prof. Bailey Willis is the leading champion of the theory that the valleys are due to the uplift of their sides owing to the horizontal compression of the crust, instead of to the subsidence of their floor owing to lack of support in consequence of the shrinkage of the internal mass of the earth. Prof. Willis therefore called them 'ramp valleys' instead of 'rift valleys'. He advocated this theory for the section of the Great Rift Valley in Palestine and went to Africa to see how far the explanation is applicable there. He found that the subsidence view is correct for the part of the Rift Valley for which it was expounded; but he holds that the rift valley along the Albert Nyanza was formed by the uplift of the walls along overthrust faults. The same action, to some extent, was suggested by Dr. Wayland (*Geog. Jour.*, **74**, p. 133), whose description of the local rift valleys as "fracture valleys running along the crests of linear upwarps" combined with the "more or less continuous sinking of the rift valley floor" agrees with the view that the essential processes were, in order, upwarp, rupture, and subsidence. The existence of overthrust faults beside Lake Tanganyika is well known; but they are possibly far too old to have produced the rift valley. As the floor of Tanganyika is 1600 ft. below sea-level, Prof. Willis admits that it must have reached its position by subsidence. Prof. Huxley accepts the ramp-valley theory for the area for which its author has abandoned it, and adopts the existence there of a great high-level lake. The evidence for that lake is considered by Prof. Willis, who has had exceptional opportunities for the study of old lake terraces, and he denies its existence.

It would be premature to discuss Prof. Willis's theory of the origin of these valleys until the issue of his full work on the subject. He attributes the valleys to the expansion of vast subterranean discs by re-crystallisation of the constituents under the rise in internal heat. One such disc he believes to underlie the Victoria Nyanza, and its expansion has forced up the land along its margins and thus formed high ramps. The alternative view is that the rift valleys were caused by movements of the crust due to extensive subsidences, of which the largest formed the basin of the Indian Ocean and broke across the former continent of Gondwanaland.

Prof. Bailey Willis is the leading adherent of the permanence of oceans and continents. He thinks that the continents have been connected by isthmus-lands, like Central America, but that the main ocean basins have existed throughout geological time. He therefore denies the existence of Gondwanaland and, in reference to the rift valley in Palestine, the formation of the Levant by the foundering of its floor. In his discussion of the problem, he appears to consider that the supporters of the subsidence theory of rift valleys deny any uplift along their course or of their edges. But the subsidence of a band below a rift valley would have pushed the underlying material sideways; and this movement would have upraised the edges. Suess called this effect the *Aufwulstung* of the edges. Ruwenzori may have undergone some such uplift, though its topography, so far as can be judged from the maps, seems in favour of its having remained a high massif for a very long period.

Prof. Willis wonders how the gentle slopes up which the Uganda railway climbs on to the Mau plateau can be reconciled with the ordinary rift valley theory; but the features of that part of the margin of the rift valley appear due to the Oligocene faulting, and the scarp was not renewed by later faulting. Prof. Willis represents, on the tension and subsidence theory, that there must have been a line of super-Himalayan mountains along the Rift Valley in Kenya Colony, and says that there is no trace of any such mountain chain; but on the view that the subsidence of the Indian Ocean was accompanied by a widespread uplift in East Africa, the highest part need not have been more than a few thousand feet above the present margins. The irregularities in level of the margins of the rift valley appear all that need be expected as the relics of its drainage channels.

Amongst the many interesting contributions in Prof. Willis's volume is a record of an egregious failure of water divining, and the welcome term 'island-mounts' instead of *inselbergs*. But his statement that those who "said that Paul du Chaillu lied were wrong" repeats a widespread misunderstanding; they who said that the skins, which du Chaillu sold as those of gorillas that he had shot at close range when in deadly peril, had been caught in native traps, were unquestionably right.

J. W. GREGORY.

Human Monstrosities.

The Mystery and Lore of Monsters: with Accounts of some Giants, Dwarfs and Prodigies. By C. J. S. Thompson. Pp. iv + 256 + 32 plates. (London: Williams and Norgate, Ltd., 1930.) 15*s*. net.

MR. C. J. S. THOMPSON, who is known to medical men because of contributions made to the history of their art, has published, in bookform, gleanings he has gathered concerning the ancient lore of human monsters. His book will make a wide appeal, not only to those who are interested in the 'lore of monsters', but also to embryologists who are in search of the rarer aberrations undergone by the human body in the course of development. His text is clear and easy, and is enriched by many illustrations of 'prodigious births' which have adorned the records published by writers in former centuries.

Down to the end of the seventeenth century, it is difficult to know whether the abnormalities which are described had actually been seen by authors or only imagined. Lycosthenes, who wrote "Prodigiorum ac Ostentorum Chronicon" in 1557, illustrated by 1500 woodcuts, gives the following account of the 'terrible child' who was "born in Craconia of noble parents. It had bright fiery eyes, the mouth and nostrils like an oxe's. It had long hornes and a black fur like a doggs and on its breasts, faces like apes. It was splay-footed, and splay-handed. The feet were like swan's feet and it had a tayle twined upwards, that was crooked backwards about half-an-ell long. It was born and lived four hours and then spoke thus, '*Watch, the Lord our God comes*'."

The ancient Babylonians, Egyptians, and Greeks believed any combination of human and animal parts was possible; indeed, the study of ancient records is a study of human credulity rather than of embryological aberration. We are not surprised, however, that George Buchanan, the Scottish historian, who did so much to strip myth from truth in the records of his own country, should write rationally and with interest of monsters. "About this time (1490)," he says, "a strange kind of monster was born in Scotland. In the lower part of the body it resembled a male child, differing nothing from the ordinary shape of the human body, but the trunk and all other members became double and were distinct both in their use and appearance. The King caused it to be carefully brought up and educated, particularly in music, in which it wonderfully excelled. It learned different languages, and in their various inclinations the two bodies appeared to disagree between themselves, sometimes disputing, each preferring different objects and sometimes consulting for the common pleasure of both."

Mr. Thompson cites examples which taxed the learning of clergymen as well as of surgeons. The clergymen had to determine whether the monster was to be regarded as being made up of two souls or of only one, and whether, in baptising, two names had to be given or if one would suffice. The surgeon's perplexities were of a less metaphysical nature: Was the bond which joined two bodies of a kind which could be severed? If one part of the monster died, could the living part be saved? Modern surgery is now attacking these problems—often successfully.

In the eighteenth century, the study of monsters entered its scientific stage; schemes of classification, based on a knowledge of normal development, were devised; only in the present century did we enter the further stage of learning how monsters could be produced experimentally. Mr. Thompson has brought a wide and accurate knowledge to bear on "The Mystery and Lore of Monsters".

Biochemistry in America.

The Development of Physiological Chemistry in the United States. By Prof. Russell H. Chittenden. (American Chemical Society Monograph Series, No. 54.) Pp. 427. (New York: The Chemical Catalog Co., Inc., 1930.) 6.00 dollars.

THIS is a review of the evolution of physiological chemistry in the United States during the past fifty years. Prof. Chittenden has seen it all happen, from the starting of the first laboratory of physiological chemistry in Yale in 1874 until the present day, when practically every university in the country has a staff of competent investigators and well-equipped laboratories, besides the agricultural experiment stations and laboratories of the Government bureaux at Washington, which are the admiration of the scientific world.

At the beginning, it was necessary for American and British students to go to Germany for training—Chittenden went to Kühne in Heidelberg in 1878. A start had been made in Germany in the study of natural products, although the golden age did not commence for another decade, when Kossel and Emil Fischer in particular introduced more precise chemical accuracy into the field; the reproach that "Thierchemie ist Schmierchemie" had been too true.

The author traces the development of laboratories, equipment, societies, and journals, and then gives a running commentary, arranged mainly under schools, on the workers whose activities have increased knowledge.

The work of W. O. Atwater on nutrition will always remain a classic, and his dietary studies led to the first standard diet. His work with the respiration calorimeter, later followed up with such success by Benedict, has been prolific of results.

The study of vegetable proteins was taken up energetically by Osborne from 1891 onwards; he produced more than one hundred publications, which form the basis of the chemical knowledge of this group.

H. D. Dakin's work on the amino acids and his β-oxidation hypothesis, that of Walter Jones on nucleic acids, of P. A. Levene on nucleic acids and the carbohydrate group, are only a few instances of the long list of positive achievements which are detailed. They suffice to show that the organic chemist has definitely entered the field of natural products. The task of unravelling their constitution and their molecular structure by analysis is near completion, many of them have been synthesised, a hint has been gained of their function, yet how much remains to be done. The best men in the best-equipped laboratories the world over have problems enough for many years to come. How, for example, are meat and milk made from grass? Will it take another half-century to answer this question?

The book is one of the American Chemical Society Monograph Series, and is produced in clear type with the high standard that characterises the series. E. F. A.

Short Reviews.

Die Beschneidung bei Mann und Weib: ihre Geschichte, Psychologie und Ethnologie. Von Felix Bryk. (Monographien zur Ethno-Psychologie, herausgegeben von F. Bryk und C. L. Hansen, Band 1.) Pp. x + 319. (Neubrandenburg: Gustav Feller, 1931.) 15·60 gold marks.

THE need for detailed monographs on genital mutilations has long been felt, and above all a sound and scholarly treatment of circumcision was desirable. This book, however, scarcely fulfils that want. It is a very general account of a number of different operations, but is without orderly plan, and the author has clearly been unable to deal satisfactorily even with the limited number of authorities he quotes, or to appreciate the vast distribution of the practices under discussion. Instead of confining himself to the matter on hand, he wanders off to discuss male infibulation, *ampliatio vaginæ*, perforation of the clitoris, and many other similar practices. The result of this is that the author becomes lost in his own maze: the very multiplicity of the customs bewilders him, and he ends by coming to few new conclusions at all. He quotes largely from Biblical sources, whilst failing to realise that the ideas of earlier civilisations were better worth his ink. Whilst rightly rejecting Reitzenstein's attempts to find evidence for circumcision in palæolithic times, he fails to understand that the ritual significance of the custom is the point on which his attention should have been focused.

According to the author, circumcision of the male arose partly at least from the desire to imitate domestic and other animals which were observed in copulation. To this was added the supposed desire on the part of early man to increase the ease of the process in himself, and the recognition of the hindrance a partial or total phimosis caused to him.

Thus this volume is merely a sketch of genital mutilations, and as such is useful for the purposes of summary. The illustrations are well chosen, the printing good, and the indexes of value. But as a guide towards solving the mystery of circumcision the book is not helpful. It is an epitome of current theories and we cannot pretend that these are convincing. Circumcision still awaits its shrewd interpreter. E. J. DINGWALL.

Femcifrede Logaritmer og Antilogaritmer (Five Figure Tables of Logarithms and Anti-Logarithms). By A. K. Erlang. Udgivet ved (edited by) R. E. H. Rasmussen. Pp. 48. (København: G. E. C. Gads Forlag, 1930.) n.p.

(2) *Addition-Subtraction Logarithms to Five Decimal Places.* By L. M. Berkeley. Pp. xii + 134. (New York: White Book and Supply Co., 1930.) 3.25 dollars.

(1) THIS is a clearly printed table of logarithms and antilogarithms to five places with a four figure argument and mean differences. A seven place table of $\left(1+\frac{r}{100}\right)^n$ for $n=1$ to 9 and $r=0{\cdot}00$ to $7{\cdot}50$ is appended.

(2) If a is greater than b, the addition logarithm of $\log a$ and $\log b$ is $A=\log\frac{a+b}{a}$ and the subtraction logarithm is $S=\log\frac{a}{a-b}$, so that $\log(a+b)=\log a+A$ and $\log(a-b)=\log a-S$. Evidently A and S are functions of a/b only so that $\log a-\log b$ can be used as argument for a table of A and S. The present table is arranged in triple columns corresponding to $\log n$, $\log\frac{n+1}{n}$, $\log(n+1)$ so that the central column is the addition logarithm of two logarithms which differ by $\log n$ and the subtraction logarithm of two logarithms which differ by $\log(n+1)$. This central column proceeds by unity in the last figure so that A and S are found without interpolation. The table is thus in effect a critical table, but is not arranged in the form usual in such tables. The use of addition and subtraction logarithms allows long trains of calculation to be performed without reverting to natural numbers, for

example $\sqrt[5]{(a^5+b^6+c^7)}$, $\cos b \cos c + \sin b \sin c \cos A$. Incidentally from the value of $\log n$ the table gives without interpolation $\log (n+1)$, $\log (n-1)$, $\log \frac{n+1}{n}$, $\log \frac{n-1}{n}$, and the logarithms of the reciprocals. This is a most useful table for five figure calculations with logarithms.

L. M. MILNE-THOMSON.

Advanced Trigonometry. By C. V. Durell and A. Robson. Pp. viii + 335. (London: G. Bell and Sons, Ltd., 1930.) 8*s*. 6*d*.

THIS volume, dealing mainly with analytical trigonometry, provides an excellent school course for senior scholars. It embraces the logarithmic, exponential, and hyperbolic functions; expansion in power series; projection and finite series, and complex numbers. No hesitation has been shown in using the methods of the calculus throughout, and a commendable feature is the development and application of the powerful principle of inequalities. The section devoted to complex numbers, occupying considerably more than half the book, is especially noteworthy for its clearness and sound treatment. As the authors point out, the interest and value of higher trigonometry lies in its being an introduction to modern analysis and, for this reason, the methods by which results are obtained are of more importance educationally than the results themselves. This is the basic principle upon which the book has been written.

The extreme rigour which characterises modern analysis is, as every teacher knows, quite out of place in a school course, with the consequence that many of the standard treatises are unsuitable for teaching purposes outside the universities. The present volume therefore, written by experienced teachers who fully appreciate the difficulties in the work of mathematical instruction, can be thoroughly recommended as a fresh and inspiring survey of a difficult section of school mathematics.

Rationalization. By Dr. James A. Bowie. Pp. 36. (London: Sir Isaac Pitman and Sons, Ltd., 1931.) 1*s*. net.

ONE of the best signs for the future of British industries is the interest now being taken in problems of industrial reorganisation. In this connexion, 'rationalisation' has frequently been proposed as a remedy for industrial ills, but the meaning of the term is vague and may serve indeed rather to obscure than to clarify discussion of these problems. Dr. Bowie has performed, therefore, a real service in providing a critical examination of its implications and methods in this pamphlet. Defining rationalisation as the *conscious* control and readjustment of industry, he points out that it has two sides: one external, concerned with the grouping of a large number of previously independent, competing enterprises, and the other internal, concerned with the efficient organisation within each unit of the functions of production, finance, personnel, and distribution. In examining the various implications of his subject, Dr. Bowie discusses such questions as vertical versus horizontal combinations, the mechanics of rationalisation, the planning of production, the problem of labour, the problem of control, and labour co-operation.

Constitution et thermochimie des molécules: les constituants moléculaires, les liaisons intramoléculaires, la valeur énergétique des liaisons. Par Albert Gosselin et Marcel Gosselin. Pp. vii + 231. (Paris: Les Presses universitaires de France, 1930.)

THIS volume contains a brief account of the three types of valency which are now generally recognised as definitely distinct in character. The descriptive portion is followed by thermochemical data on the heats of formation of compounds from which the thermal values for the energy required to rupture different bonds in complex molecules are calculated. These in turn are employed to elucidate the structure of numerous compounds. Some of the formulæ proposed, for example,  $H_2\text{-}C\langle{}^{.H}_{.H}$ for methane, $H_2\text{-}N\text{-}.H$ for ammonia, and $NH\text{-}CO\text{-}NH_3$ for urea, are so different from those usually accepted, and the evidence advanced in favour of them is so problematical in character, that the book must be regarded as one which might be somewhat unsafe as a text-book. It does, nevertheless, contain many interesting observations on reactivity of organic compounds.

E. K. R.

Synthetic Inorganic Chemistry: a Course of Laboratory and Classroom Study for First Year College Students. By Prof. Arthur A. Blanchard and Prof. Joseph W. Phelan. Fourth edition. Pp. xii + 352. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 15*s*. net.

THIS book contains a course of experiments and preparations in inorganic chemistry covering all the groups in the periodic system. Full details of the experimental procedure are given. The elementary theory of ionisation and that of mass action are included, and numerous questions and problems are given both in the text and at the ends of the chapters. The book is similar in plan to Biltz' "Laboratory Methods of Inorganic Chemistry", but is more elementary, and it provides a clear and useful course of experimental work in preparative inorganic chemistry, which could supplement the instruction in analysis usually given to degree students. Many of the preparations are suitable for pupils in the higher forms in schools.

Some Modern Mediums. By Theodore Besterman. Pp. xi + 189 + 4 plates. (London: Methuen and Co., Ltd., 1930.) 7*s*. 6*d*. net.

IN this book, the author has made a genuine attempt to present his case in a more or less unbiased manner. He is quite honest in his admission that several well-known mediums have turned out to be frauds. Mrs. Piper he considers perfectly genuine. So much evidence with regard to mediumistic performances consists of a 'has not been found out' attitude, that it is interesting to read evidence of a positive nature.

Deep Oil-Well Drilling.

IT is perhaps not generally known that the long-projected depth of a 10,000 ft. oil-well was reached recently by the drilling of a hole to 10,030 feet in Ventura County, California, by one of the leading petroleum corporations in that State. The well was actually a 'wild-cat' put down to prove a possible extension of the Rincon field, though undoubtedly there was behind the venture a determination to create a depth record. Drilling was started in 1929, delay in completion occurring as a result of fire and technical difficulty last year.

This is the deepest oil-well, if not boring, in the world as yet on record. Apart from a matter of doubtful economics, especially in view of the present situation in the oil industry, the result undoubtedly is a great achievement in the history of petroleum engineering, and bears eloquent testimony to the high state of efficiency of both technical skill and plant existent in the industry to-day.

Deeper drilling for oil and deeper workings for other natural resources are contemplated and planned to-day with much vigour. Such propositions would have been condemned a few years ago. In the case of petroleum, while area may be limited for structural or other reasons, the possibility of productive oil-measures lying beneath the known pay-horizons is often considerable, particularly where a thick series of sediments comprising multiple reservoirs is involved. The limit to their exploitation is either that dependent on commercial policy or current economic conditions, or is one of plant design and performance. If cost is not a first consideration, it is clear from this new record that drilling equipment can be built and operated to carry a boring successfully to even greater depths; in fact, it is unlikely that American oil engineers will rest until the two-mile hole has been drilled and until commercial production from such a distance has been realised.

It is this last factor which constitutes the steadying influence on any wild projects, since it pays no one to put down deep wells simply to finish up in an unproductive stratum, as was the case with this Californian well. Even supposing such a well is successfully drilled—that is, without unusual hazard in the shape of fire, abnormal water conditions, mechanical faults, bad deviation from the vertical, and so on—unless there is sufficient gas to cause the oil to flow easily to the surface, compressors and pumps have to be installed, and production costs mount up to a prohibitive level at the outset.

In other mining spheres, deep borings are usually of an exploratory character, with the view of subsequent underground developments calling for human activity at or near to the depths attained. Unlike oil, controlled mechanically from above, the winning of ore, for example, demands actual contact with the reserves, so that in the long run the depth limit in this case is that determined by physiological factors. Despite the great depths at which it is possible for man to work underground, it would seem inevitable that human endurance will place a limit on depth working sooner or later (it is clear from South African mining tendencies that that limit has not yet been defined), and that projects and accomplishments in the realms of oilfield drilling will far outstrip those in other fields of subsurface exploitation.

The influence which this deep oil-well drilling campaign has had throughout America, and incidentally in other countries as well, has been enormous. It is one of the primary causes of the existing glut of petroleum and market stagnation. Where formerly extension of productive area was sought superficially, geological field survey has given much of its place to subsurface calculations and extensions in the third dimension. Geophysical methods have played an important part in this reversal of technique. Other things being equal, the risks are probably far less in deepening a field where the log is known for some thousands of feet, than in opening up new territory; probably the latter proposition is far more costly in any event. Where geological knowledge presupposes that older formations or horizons are potentially more productive than those long exploited, then, given the plant to penetrate successfully those lower levels, it is obviously rational to test the theory as thoroughly as possible. The fact that many of the wells already down can be deepened, thus saving the cost of complete new rigs, has also influenced this policy, and for some time to come it is evident that all over the world, where increased production of oil is sought, the American example will be zealously followed.

There is another and equally important aspect of the matter. The achievement of holes in the earth's crust to such depths as this Californian well should direct attention to the possibilities of making accurate physical measurements to confirm or modify data which have previously been based on calculation. It may be presumed that some scientific advantage was taken of the progress of this particular well, though we have not heard as yet that this was so. The measurements of thermal and pressure gradients, to cite only two lines of investigation, would be most valuable in such a case as this; had the well been productive, comparisons between the oil and water from such depth and similar fluids from shallower horizons would furnish data, both chemical and physical, still much needed to square our ideas of petroleum genesis.

If deep oil-well drilling, as a technique, is to advance further (and there is little doubt but that in time it will do so), then, given the opportunity, science is likely to gain in yet another direction from industrial operation. Failure to bring in a two or three mile oil-well successfully may find its mitigation in the advancement of knowledge which carefully controlled operations should bring about. The 10,000 ft. oil-well establishes a record, but it also has been the cause of a great human effort to produce something better. This is perhaps its vindication, if such need be.

The German Bunsen Society in Vienna.

By Prof. Fritz Paneth (Königsberg i. Pr.).*

THE German Bunsen Society for Applied Physical Chemistry and Electrochemistry holds a general meeting annually, and this year the meeting took place in Vienna on May 25–28. Some 350 physicists and chemists from Germany and Austria attended the meeting and, as is usually the case, there were present a number of representatives from several other countries, including Switzerland, Czecho-Slovakia, Hungary, Poland, Holland, Sweden, Spain, the United States of America, and Great Britain. From the last-named country no less than eight well-known chemists were present.

In the Bunsen Society it is customary to fix upon a main topic for the lectures, and this principle was again adopted. Last year the main topic was of an essentially theoretical nature, so that this year, in view of the fact that the Bunsen Society is intended to serve the interests also of applied physical chemistry, a topic of importance in technical work was chosen as the subject for discussion. The title was "Advances in the Science of Metals, and their Applications to Light Metals". The president of the Bunsen Society had invited five members to give lectures in the nature of a comprehensive survey on the selected theme, and these included Prof. G. Tammann, who celebrated his seventieth birthday during the meeting on May 28, and was the object of numerous expressions of esteem. Amongst others, there was an address written by Prof. Nernst, which was presented to him during the first session by the president of the Society, and in which his great services to the most divers branches of physical chemistry were emphasised.

The first comprehensive survey was given by Prof. R. Becker (Berlin) on "Electrical and Magnetic Properties of Metals". He commenced by pointing out that the old classical theory, which treated as a gas the whole of the free electrons present in a metal, is entirely inadequate in the face of two facts of experience; it is unable to explain either why the electrical resistance vanishes with diminishing temperature, or why the free electrons make no contribution to the specific heat. Both points are cleared up by two profound alterations which have to be made to the classical picture, according to quantum mechanics. The individual electron is not to be described as a point charge, but as a wave function, and the interference of the electron thus rendered possible brings about the disappearance of the resistance in a lattice which is not disturbed by thermal movement. On the other hand, Pauli's principle (Fermi statistics) becomes effective in the sense that the free electrons are unable to supply any appreciable contribution to the specific heat. The practical application of the quantum mechanical picture of the metallic state envisaged by modern theoretical physics is, for the time being, however, held up by mathematical difficulties.

The next lecture, by Dr. G. Masing (Berlin), was entitled "Age-Hardening, especially on the Basis of Experience with Light Metals and with Alloys of Beryllium". Masing started off from the effect discovered by Wilm in 1909 with duralumin, in which a marked hardening (*Vergütung*) of alloys can be attained by quenching the material from a high temperature, and afterwards storing it at ordinary temperatures. This phenomenon, which has been observed not only with alloys of aluminium, but also with alloys of copper and other heavy metals with beryllium or silicon, as well as with several varieties of steel, etc., has not hitherto found a wholly satisfactory explanation. It is certain that a necessary condition for the hardening is that supersaturated mixed crystals are produced by the quenching; hence we must assume that the hardening is somehow associated with an alteration of these supersaturated mixed crystals. On the basis of all the available evidence, especially the results of X-ray investigations, Dr. Masing was of the opinion that the hardening can be regarded generally as an accompaniment of the separating out of a second type of crystal from a mixed crystal. The details of this segregative process, and accordingly also of age-hardening, are probably different, however, for different alloys.

The third speaker was Prof. Tammann (Göttingen), on the subject of "Recrystallisation". It is well known that the structure of a specimen of metal can be fundamentally altered by rolling or forging. This is due to the fact that the crystallites become drawn out into plates or fibres by slipping on defined crystallographic planes. In this way the originally random orientation of the crystallites passes over into a more or less completely ordered form. The physical and chemical properties of the metal, as well as its elastic properties, change in this process, and we may thus assume that, as a result of the displacement along the slip-planes, an alteration takes place also in the atoms themselves. If we increase the temperature of the specimen, the original properties tend to return, and in every metal this recovery of the crystallites takes place within a different range of temperature. With further increase of temperature, fresh boundaries and individual small grains, which can be detected by etching, make their appearance in the plates or fibres. The orientation of the bodies with respect to each other is different, and for temperatures in the neighbourhood of the melting-point a random orientation of the grains is produced; at the same time the grains increase in size, and the last traces of the cold-working vanish.

In continuation of the subject, Dr. Sachs (Frankfurt a. M.) discussed "Problems of the Science of Metals in the case of Aluminium and

---

* Translated by Dr. R. W. Lawson.

Aluminium Alloys", whereby in particular he dealt with the technically important cohesional properties of individual crystals, of rolled alloys, and of cast alloys. Attention was directed to the relations between the plastic properties of metallic crystals and their lattice structure, and emphasis was laid on the differences which exist in the formation of alloys of aluminium as compared with those of copper, silver, and gold. Another aspect of aluminium alloys was discussed, namely, the complicated hardening effects, which may lead to increases by two orders of magnitude in the cohesive properties, as compared with the original modulus of shear of the crystal. Dr. Sachs is inclined to attribute this to changes in the homogeneous phase. Later, the harmful influence of a gas content on cast alloys was discussed theoretically, and finally he considered the process whereby aluminium is protected against corrosion by means of a compact oxide film produced electrolytically.

The last of the general surveys on the subject was presented by Dr. E. Schmid (Berlin-Dahlem). He discussed the "Physics and Metallography of Magnesium", in which connexion he dealt particularly with those differences which are based on the hexagonal crystal structure of magnesium and its alloys, in contrast to the large group of cubic technical metals.

The president of the Society had not only drawn up the programme of the session at which the five general surveys just mentioned were delivered, but he had also recommended that in the choice of the individual lectures preference should, so far as possible, be given to topics which are related in some way with the main topic of the meeting. Accordingly, in the other sessions at which freely selected individual lectures were delivered, topics taken from the science of metals were in many cases discussed. In view of the large number of these shorter papers—in all about sixty single papers were read—it is only possible here to direct attention briefly to a few of them.

Dr. W. Schmidt (Bitterfeld) dealt with the "Technology and Application of Electron-Metal", and made detailed statements on the components of this alloy, which is so valuable owing to its lightness, and also on the process of refining and the method of working it. Dr. W. Kaufmann (Frankfurt a. M.) reported on the "Vaporisation of Magnesium in a Vacuum", and illustrated his remarks by the demonstration of interesting preparations. Dr. Seith (Freiburg) communicated the results of experiments that he had performed in collaboration with Prof. Hevesy on "Diffusion in Metals". The diffusion of a metal in itself (self-diffusion) was treated as a limiting case of the diffusion of one metal in another (foreign-diffusion), and it was shown that in metals self-diffusion is always very slow, large velocities of diffusion only being able to manifest themselves in certain cases of foreign-diffusion. For example, the diffusion of gold in lead at 150° C. amounts to 4×10^{-3} cm.^{2} day^{-1}, whereas lead in lead at the same temperature has a diffusion coefficient of only 8×10^{-10} cm.^{2} day^{-1}. Papers by Dr. Pietsch (Berlin) and Dr. Schwab (Munich) dealt with the "Activity of Complex (*Mehrstoff*) Catalysts" and the question of the active centres in hydration catalysis.

More detailed reference may be made to the lecture by Prof. K. Przibram (Vienna), who presented a very illuminating contribution to the topic of the main lectures, more especially to the lecture of Prof. Tammann; Przibram has succeeded, in a special case, in permanently recording cinematographically the process of recrystallisation.

It is well known that rocksalt assumes a yellow colour under the influence of the rays from radium. The coloration takes place more rapidly and penetrates more deeply when the mineral has been subjected to a uni-directional pressure of more than 100 kgm./cm.^{2} before treatment with the rays; rocksalt which has been compressed by a force equal to the weight of a few thousand kilograms becomes almost black in a short time when rayed by means of radium. About two years ago Przibram observed that such specimens, after some time, again show clearer regions, which slowly grow. Since the deeper coloration of the compressed salt was attributable to disturbances of the crystal lattice, it was necessary to conclude that the reoccurrence of clearer patches was due to a progressive healing up of the disturbed lattice, that is, to recrystallisation, a conclusion which could be verified simply by cleaving the specimens, when large reflecting crystal surfaces were revealed as the cleavage planes of the clear patches, whereas the black part showed no cleavage. It could also be proved by means of X-rays that the clear regions again possessed an orderly crystal lattice.

A method thus presented itself of conveniently following up the recrystallisation of the compressed rocksalt, and even of recording it cinematographically by 'stealing a march on time'. The process in the production of the film was the following. A small slab of rocksalt was chosen, which, a few weeks after the above described treatment, revealed a beautifully regular and almost square grain of recrystallisation. Forty exposures of this slab were taken daily—twenty in the morning, one directly after the other, and likewise twenty in the afternoon—and this process was continued for a period of two months. The exhibited film showed first the compressed specimen of rocksalt traversed by cracks, with the above-mentioned clear recrystallised grain in the left upper quadrant. The gradual growth of this grain was clearly to be seen, and it was also evident that the marked horizontal crack separating the two left quadrants provided an insurmountable obstacle to the further growth; the corner of the grain approaching it became blunted. Apart from the first-mentioned grain, a number of other grains formed in the course of time, and these likewise grew, until finally a large part of the specimen appeared in the recrystallised state.

This first film illustrating recrystallisation is naturally still somewhat defective. There is, however, no doubt that when it has been arranged to take the photographs at regular intervals of, say, an hour, day and night, by means of an automatic device, it will be possible to undertake accurate measurements of the velocity of recrystallisation, with the aid of the film. The method is already very useful for the demonstration of the process of recrystallisation.

Mention should be made of a few papers which had no direct connexion with the main theme. Dr. Werner Kuhn (Karlsruhe) presented a communication on "Single and Superposed Absorption Bands and their Behaviour with respect to Optical Activity". With *d*-camphor Dr. Kuhn has found that an absorption band which has usually been considered single is in reality a superposition of a weaker and a stronger band. He was led to this view by the observation of certain deviations in the behaviour of camphor as compared with that of other optically active compounds. Dr. Fromherz (Munich) spoke on "A Spectroscopic Investigation of the Conditions of Dissociation of the Halides of Metals in Solution". Whereas the absorption curves of light in aqueous solutions of the halides of the alkali and alkaline earth metals are essentially independent of the concentration as regards their shape and position, up to the highest concentrations, new absorption bands of association products make their appearance alongside the absorption bands of the hydrated ions in aqueous solutions of lead, thallous, cadmium, and mercury halides, and they arise to an increasing degree as the concentration of the solutions is increased. From the spectral position of the bands and the dependence of their height on the concentration of the contributing ions, it has been possible to determine the nature of the association products, the dependence of the degree of association on the concentration, and hence the equilibrium of association in the solutions. Dr. Beutler (Berlin) gave an account of a piece of work which was concerned with dissociation as a result of collisions of the second kind, and in which, in particular, the splitting up of the hydrogen molecule into a normal and an excited hydrogen atom by means of excited neon atoms was followed up spectroscopically. Prof. W. A. Noyes (Urbana) pointed out that the formula proposed by Mecke on the basis of spectroscopic data for nitrogen dioxide $O=N-O-$ is in good agreement with the views on 'shared' and 'unshared' electrons which have been derived from the chemical behaviour of nitrogen dioxide.

Dr. Frankenburger (Ludwigshafen a. Rh.) has continued with his collaborators the attempts to combine hydrogen or nitrogen with highly disperse metals. Their method is to separate iron or nickel from the vapour phase; the resulting metals, which are always at first in an extremely finely divided form, join up to form larger particles if this process of collective crystallisation is not suitably prevented. Frankenburger realises this by arranging that sodium chloride is deposited from the vapour phase simultaneously with the metal. When the molecular ratio $NaCl : Fe$ was increased to 2000 or 3000, it was found possible to combine up to six molecules of hydrogen with each atom of the separated iron. We are here obviously dealing with weak affinities between metal atoms and gas molecules, forces akin to those of van der Waals in the gas theory. In the discussion, Prof. Biltz (Hannover) suggested that the phenomenon is perhaps in its nature related to the attachment of five or six molecules of water of hydration to the chemically non-reactive atoms of argon, krypton, and xenon.

Prof. Paneth (Königsberg) reported on the continuation of the investigations on free methyl and ethyl, which were intended to bring clarity with regard to the mechanism of the disappearance of the free radicals. If helium instead of hydrogen is used for the transport of the radicals, their activity falls off with the same velocity as in hydrogen; from this and from related observations it is concluded that a reaction takes place with the vessel walls. Whereas in a glass tube the radicals can be transported more than half a metre by a rapid gas flow, a metal mirror 1 cm. in length introduced into the tube suffices to bind the radicals quantitatively. On the basis of formulæ derived from the kinetic theory of gases by Prof. K. F. Herzfeld (Baltimore), we can calculate from these results that every free radical is bound by a single impact on a metal capable of reaction, whereas from amongst one thousand radicals incident on a glass wall only about one is not reflected. From the discussion on this paper we may direct attention especially to the remarks of Prof. Bodenstein (Berlin), who mentioned similar observations in the combination at glass walls of 2 Cl to form Cl_2.

It was decided to hold the next meeting of the German Bunsen Society at Münster, in the year 1932.

Obituary.

SIR HUGH BELL, BART., C.B.

THE north-east coast of England will have bitter reason to remember for long the first half of the current year, because this highly industrial corner of England has lost by death a greater number of its leading industrialists than can be remembered in any similar period. The names of such men as Sir Arthur Dorman, Sir Charles Parsons, Andrew Laing, Sir Archibald Ross, and now Sir Hugh Bell, all dead since the beginning of the year, show how severely it has suffered; such losses would be serious enough at any time, but at a time of crisis like the present, when men of experience, judgment, and knowledge are so badly needed, the loss is even exceptionally deplorable: for, as the above names show well enough, these were men who were known and honoured not only in their own district but also in all industrial circles throughout the world, and no one was better known or more highly honoured than the man whose loss we mourn to-day.

Sir Hugh Bell was born at Walker-on-Tyne on Feb. 10, 1844, and was thus more than eighty-seven years of age when he died, but fortunately he retained his keen intellect and active interest in affairs down to the end. He was the eldest son of a famous father, Sir Lowthian Bell, well known for his classical researches into the chemistry of the blast-furnace, and an ironmaster of high repute. The son received his first education at Merchiston Castle School, Edinburgh, but at fifteen years of age, in 1859, he went to Paris and studied chemistry at the Sorbonne under Ste. Claire Deville, continuing his studies afterwards at the University of Göttingen. His stay abroad was not, however, a very lengthy one, for in 1862, at eighteen years of age, he had returned to England and commenced to take part in the family business of ironmaking.

Sir Lowthian Bell was one of the first to appreciate the importance of the Cleveland ironstone, and thus played an important part in the development of modern industrial Middlesbrough, the centenary of the foundation of which was celebrated last week. Sir Lowthian Bell with his brothers erected blast-furnaces at Port Clarence, and Hugh Bell was made manager of these works. The father formed his business into a public company under the title of Bell Brothers, Ltd., in 1899, and Hugh Bell was the managing director; meanwhile, steel works had been added to the blast-furnace plant at Port Clarence. Sir Lowthian Bell died in 1904, and Sir Hugh Bell succeeded to the baronetcy in that year, and was made chairman of the company in succession to his father. Sir Hugh Bell continued to direct the fortunes of Bell Brothers, Ltd., until this became one of the important iron and steel making firms of the country. It was taken over in 1923 by Dorman, Long and Co., Ltd., Sir Hugh Bell becoming a director of that company, with his lifelong friend, Sir Arthur Dorman, as chairman. After Sir Arthur Dorman's death on Feb. 12 of this year, Sir Hugh was made chairman of Dorman, Long and Co., Ltd., so that this great firm has had the sad experience of losing two chairmen by death within a few months of each other. Sir Hugh Bell was also chairman of the firm of Pearson and Dorman, Long, Ltd., the interests of which lay more particularly in the development of collieries in Kent, whilst he was also chairman of the Horden Collieries, Ltd., an important colliery in East Durham. It may be added as a matter of historical interest, which will, however, be fresh in the minds of most people, that Messrs. Dorman, Long and Co., Ltd., took over the famous firm of Bolckow, Vaughan and Co., Ltd., so recently as 1929, and Sir Hugh Bell necessarily took his share in this increased responsibility. He was also a director of the London and North-Eastern Railway Company and of numerous other technical and industrial concerns.

In 1869, Sir Lowthian Bell took a prominent part in the foundation of the Iron and Steel Institute, the object being to afford a free means of communication between all interested in iron and steel manufacture, especially in its technical and scientific aspects, deliberately excluding all questions connected with wages. The first meeting of the Institute was, appropriately, held at Middlesbrough, the late Duke of Devonshire having been the first president. Sir Hugh Bell, naturally enough, became an original member of the Institute, being at the time of his death one of the last living representatives of that class; he became president of the Institute in the year 1907, and occupied the chair for three years. The Bessemer gold medal, the highest distinction that the Iron and Steel Institute can award, was founded in 1873 by Sir Henry Bessemer, and it was awarded to Sir Hugh Bell in 1926 in recognition of his eminent services in the cause of iron and steel manufacture. He was also an original member of the Institute of Metals, founded in 1906.

Merely to recount the work of Sir Hugh Bell as a successful ironmaster would, however, be to give a very limited and one-sided view of his activities. He was, above all, a great public servant, and rendered services to the community of which it is difficult to speak too highly. He was Mayor of Middlesbrough on three occasions, in 1874, 1883, and 1910, and he played a prominent part in the conversion of the river Tees from a shallow, dangerous, and almost useless stream into a wide and navigable river, capable of accommodating some of the largest cargo carriers now afloat. This particular work was done by the Tees Conservancy Commission, which was founded in 1852, and of which Sir Hugh Bell was chairman for the last thirty years, during which his shrewd foresight and bold enterprise were instrumental in guiding the work of the Commission to its present successful issue. It is perhaps fortunate for the nation that Sir Hugh Bell's attempts at entering Parliament were unsuccessful; he contested Parliamentary elections on two occasions, first as a Unionist at Middlesbrough in 1892, and afterwards, when he had severed his connexion with the Unionist party because he disagreed with their fiscal policy, as a Liberal in the City of London in 1910. It is perhaps unnecessary to add that Sir Hugh Bell never missed an opportunity of showing his ardent adhesion to the principles of free trade.

As might well be expected from such a man, he took the keenest possible interest in everything pertaining to technical education, and received honorary degrees by several universities, including the degree of D.C.L from the University of Durham and that of LL.D. from the Universities of Oxford, Leeds, and Sheffield. He was a member of the Board of Governors of the Imperial College of Science and Technology, but his closest connexion with technical education was through Armstrong College in the University of Durham. Sir Lowthian Bell had been a member of the council of this College, first known as the Durham College of Physical Science, up to his death, and soon thereafter Sir Hugh Bell was elected to a seat on the council. The constitution of the College was reconstructed in 1909 under the University of Durham Act, and Sir Hugh Bell became the first chairman of the College council in 1910. He held this important post for many years, during which again his shrewd judgment and keen intellect were of the greatest value to the College. Pressure of work caused him, however, to relinquish the chair in 1923, and it is significant of the aims of Armstrong College that he was succeeded by Dr. Cecil Cochrane, whose connexion with iron manufacture is too well known to need emphasising here.

Sir Hugh Bell was a notable exception to the widely held view that an able father does not produce an able son. Although in this case both father and son were distinguished ironmasters, it must, however, be admitted that their mentalities were of an entirely different order. Sir Lowthian Bell will be remembered best for his scientific acquirements and their application to technology, whilst Sir Hugh Bell's fame is not that of a man of science, but of a man who devoted his brilliant abilities and keen insight to the service of the community. It is not too much to say that he would have been eminent in any profession or career that he had cared to take up. It is a curious comment on the lives of these two great men that Sir Lowthian Bell, eminent as his scientific acquirements were, is now seen to have thrown back the industries of coke-making and of pig-iron production, to which he devoted his life, many years by his obstinate preference for the old-fashioned beehive to the more modern retort-oven coke. The future may possibly show that his brilliant son may have retarded the progress of the nation to a similar extent by his obstinate adherence to old-fashioned free-trade principles. He appeared to disregard entirely the wise saying, *Temporibus mores sapiens sine crimine mutal*, and did not seem to realise that a policy which might have been entirely right and sound at one period of the world's history, might be disastrous under different conditions.

As is perhaps only natural in the case of a man who has succeeded in living to an age beyond that of most others, the closing years of Sir Hugh's life were saddened by the loss of many dear to him; here it is only necessary to mention the death of his gifted daughter, Gertrude Bell, who died in July 1926, and that of Lady Bell, who died a little more than a year ago.

The whole record of the life and activities of the man whose loss we mourn is that of a man of keen and penetrating intellect, a brilliant speaker, an advanced thinker, and a shrewd observer, whose keenness was, however, tempered by the geniality of his character, a man who devoted his great gifts unselfishly and unsparingly to the service of his fellow-men. HENRY LOUIS.

THOUGH the Science Museum at South Kensington was established in 1857, the development of its collections had lagged far behind those representing art; but in 1909 a number of people distinguished in science and representing technical institutions sought an interview with the President of the Board of Education in order to represent the urgent importance of developing its collections and of providing more suitable buildings for their accommodation. The result of the representation thus made was that a Departmental Committee was appointed in the following year, of which Sir Hugh Bell was the chairman, its terms of reference being to consider and report upon the condition and the future development of the Science Museum and the Geological Museum.

Sir Hugh Bell took the keenest interest in this task, and under his guidance the Committee prepared a detailed report, which was adopted by the Board, laying down the lines which the development of the Museum has since followed. The report proposed the replacement of the old buildings by others of modern type, of which the eastern and centre blocks were to be completed as soon as practicable, but the outbreak of war delayed the execution of this plan and only the former of these has as yet been constructed.

In 1913 Sir Hugh Bell was appointed chairman of the Advisory Council of the Science Museum, and in this capacity for eighteen years he watched over the development of the collections and their exhibition in the galleries of the new building in accordance with the plan devised by his Committee. Difficulties and delays occurred from time to time, and on all such occasions his tact, influence, and ready help were of the greatest value in overcoming them. He took a wide view of the influence which the museums at South Kensington might, he thought, exert, and he strongly advocated a general policy of co-operation in which each museum would not only work out its own line of policy but should also look out for and develop contact with the others in order that the various aspects of human endeavour might be more fully represented.

The Science Museum owes more to Sir Hugh Bell than to anyone, and by his death it has lost a wise counsellor, a ready helper, and a valued friend.

PROF. H. WILDON CARR.

BY the death of Prof. Herbert Wildon Carr, which took place on July 8 at Los Angeles, at the age of seventy-four years, philosophy has lost an enthusiastic student and exponent, and philosophers in many countries a friend greatly respected for his single-minded devotion to learning and beloved for his generosity and kindness of heart.

Wildon Carr's life had some of the features of a romance, including (one may be permitted to say) a singularly fortunate and happy marriage. Born in circumstances which precluded a prolonged education, he had to go out into the world at the age of fourteen. But even at that tender age he had already marked out for himself what was to be the real business of his life, and addressed himself deliberately to the task of winning as soon as possible a financial competence in order that he might thereafter devote himself to philosophy. Not often have the dreams of boyhood worked out more completely 'according to plan'. For in due course Wildon Carr enjoyed in succession the status of a member of committee of the London Stock Exchange and of a president of the Aristotelian

Society and honorary professor of philosophy in the University of London.

Nevertheless, all did not go smoothly; for the youth who set out on the philosophical quest in high hopes found himself as a man brought up against the blank wall of Humean scepticism. At a memorable dinner which Carr gave in 1911 in honour of Henri Bergson, he pictured in moving terms the sadness of his intellectual plight and hailed the French philosopher with gratitude as his rescuer. Students who have followed Wildon Carr's work during the last twenty years will, indeed, recognise how powerful an impulse he received from Bergson—an impulse which, reinforced by the later influences of Croce and Gentile, carried him forward to his own monadistic idealism.

Wildon Carr's development as a philosopher is dealt with below by another hand. It is, however, fitting to emphasise here what he did for philosophy and philosophers, apart from his output as a writer. For many years he was the honorary secretary of the Aristotelian Society, and from the death of Shadworth Hodgson onwards to the time when the state of his own health compelled him to seek sunnier skies, he might almost be said to have been himself the Society. This does not mean that he ruled it as an autocrat, seeking to make its voice his own. On the contrary, there was never a more generous appraiser of an opponent's merits, nor a scholar who sought more earnestly to let all sides of a question have the best exposition and the fairest hearing. Nor did an older philosopher ever keep a more watchful eye upon promising beginners or give them more encouragement.

Under Carr's kindly and inspiring rule the Aristotelian Society was for many years a forum where most of the notable thinkers of the day debated most of the living philosophical issues. His associates during those fruitful years knew how dear the welfare of the Society was to him, and how generously he spent upon it both his time and his material means. The solid work done by it under his guidance will be an enduring part of the monument he has left behind him; while so long as those who knew him and worked with him still live, the memory of his singularly gracious and generous personality must continue to " smell sweet and blossom ". T. PERCY NUNN.

IN speaking of Carr's philosophy, it is particularly difficult to separate the philosopher from the man. Like his first teacher, Shadworth Hodgson, he, if any man of my time did, lived the philosophic life, and, after his success in business enabled him to retire, he devoted himself entirely to cultivating philosophy in himself and others. Yet he remained rather a centre of philosophers than of philosophy, and his work was an influence rather than an achievement. He taught us, through his own devotion and through the affection he inspired, to feel that we were fellow-workers in one subject, however different in our methods of approach; and I scarcely like to think what we shall do without him. Nor was it only philosophers he brought together; he also brought science and philosophy into their wholesome and natural contact. He believed that philosophy and science belonged together, and that philosophy could not be indifferent to changes in scientific ideas such as his time had witnessed. In this he was surely right. The work of the Aristotelian Society in the last twenty years is a standing witness to his success in this effort and to its fruitfulness.

Carr owed both his strength and his weakness to his open-mindedness; and the personal hold he had over philosophers of such differing views was only the other side of his candour and his intense effort to understand and assimilate. His own originality and independence showed itself in the tenacity with which he worked out a doctrine for himself, while making use of what he was continually learning from them. You would call him markedly suggestible, and impulsive as well, so that, as each successive thinker like Bergson or Croce or Einstein or Gentile fascinated him, he devoted himself to expounding them with enthusiasm. When I knew him first, he was still a disciple of Hodgson. Afterwards he leaned towards a Humean idealism, and the idealism which began thus early he never ceased to entertain under some form or other. In the end he worked his way to a kind of Leibnizianism which was very much his own. But, as anyone may see from his latest constructive pronouncement, " Cogitans Cogitata ", it retained plain traces of the doctrines that had influenced his mind, and it would be an interesting and profitable task to follow him from his phase of discipleship up to that of mastery.

Carr's readiness to accept from others may have disturbed some persons; for my part, I admired rather the independence with which he converted them to his own uses, and always, even without assenting to him, I found him one of the most interesting and stimulating minds among my contemporaries. I still have the feeling that in dealing with relativity he was over-hasty in his deliverances. I subscribe to Bertrand Russell's statement that relativity is of immense importance to philosophy but that we do not yet quite know in what way. Carr had no doubt. He thought it had dethroned Newtonianism to make way for Leibnizianism; and I expect he was, in general, right. There was, however, a want of special authority about what he said when he was expounding the new science as science, and I understand his exciting some impatience among those who knew. But he showed philosophers the way, and that it was our duty to find material for our philosophy in a thorough understanding of this new mode of scientific thought. It would be an evil day for metaphysics if a great change should occur in men's minds about the science of things and we philosophers should go our way as if nothing particular had occurred.

In philosophy there has been a marked tendency in recent years to revert to Leibniz and monadism, but to treat the monads not as windowless, like Leibniz's, but as communicating. Carr would have nothing of it, and insisted that the monads were completely independent of each other, each "expressing" itself (the word is his own) through its own activity in its own world of what is commonly called reality or external reality. The true reals are thus the monads, the so-called world of knowledge is ideal. The crux of any such theory is its solipsism, but he avowed and defended that attitude. He evaded the objection to solipsism by making community with other individuals part of the essential nature of each individual. I do not myself see how if the universe is each man's expression, it can still contain individuals who, like himself, are independent centres of activity. Often, however, as I pressed this point upon him, he did not seem to feel that it presented a real difficulty, and he seemed to think he had met it by reference to speech and mutual intercourse. In the same way he seemed to me to make the special interpretations by individuals of the physical world too exclusive of each other, and to forget that the very pith of the doctrine of relativity is that physical laws are the same in form for every observer. Leibniz himself had God and the pre-established harmony to save his monadism: but for Carr, God was but a part of the world of each monad; and this, to my mind at least, presents difficulties.

Carr's explicit philosophy is chiefly contained in the work I have mentioned and the earlier "A Theory of Monads". But besides these and his expository books, there were others, which show what a wealth of knowledge he had, outside strict philosophy or only partially related to it; in particular, two books which he published during his Californian period, "Changing Backgrounds in Religion and Ethics" and "The Unique Status of Man". When I happened once to speak to him enthusiastically of Pascal's "Pensées", with which I had made acquaintance quite late in my life, I found that the book had been his constant companion for many years.

His assiduity and industry were immense, and if his friends knew well the sweetness of his character, the amount of work he accomplished is a witness to the strength and persistence of it. To my mind, Carr's work has been for the philosophy of our time a refreshment, and even, with all allowance for its shortcomings, a fecundation; and I must not forget the singular beauty and simplicity of his style of writing, which reflected his own directness and candour of mind.

S. Alexander.

Mr. Ernest Noel.

Mr. Ernest Noel, who died at his home, Dulaney House, Patching, Sussex, on May 20 at the age of ninety-nine years, was the doyen of the Geological Society of London. Elected into the Geological Society in 1849—P. Martin Duncan, who afterwards became a fellow of the Royal Society, was also among the chosen in that year—he had been eighty-two years on its roll, a span probably without parallel in the annals of English scientific bodies. At the date of Noel's election (he was then living at Hornsey), Sir Charles Lyell occupied the presidential chair, and Charles Darwin was a member of council. Such circumstances had provided many interesting reminiscences of contemporaries and original workers in geological and general science. Born on Aug. 18, 1831, Mr. Noel was the second son of the Rev. the Hon. Baptist Noel, who himself was the tenth son of Sir Gerard Noel, and brother of the first Earl of Gainsborough (second creation). Mr. Noel was educated at Edinburgh and Trinity College, Cambridge.

News and Views.

The summary by Sir James Jeans of a series of lectures on the annihilation of matter, delivered by him during his recent visit to the United States, which we publish as our supplement this week, is a characteristically skilful presentation of the case for the reality of this process, of which he has for some time been convinced. Although, as he indicates, the doctrine of the permanence of matter has been a leading feature of the greater part of the history of science—it dates at the latest from the time of Aristotle—supporters of the opposite idea have never been wanting. It appears to be peculiar to our own time, however, that they are to be found among followers of the 'experimental philosophy'. Yet, fantastic as the idea would have seemed to the physicists of a few generations ago, it is impossible, after considering the evidence which Sir James Jeans so ably summarises, to dismiss it as unworthy of scientific attention. The process is mathematically possible; it is certainly not fundamentally inconsistent with modern atomic theory; it provides a plausible explanation of a physical observation—the highly penetrating radiation; and it appears to be the only means of bringing order into the perplexing mass of data concerning the constitution and history of the stars. The cumulative effect of these facts, even if they are not strictly additive, is considerable, and it is not surprising that the hypothesis of annihilation is being treated with marked respect.

General acceptance of the idea, however, is out of the question until more facts of observation are available. Sir James remarks that "the majority of astronomers think it probable . . . while many, and perhaps most, physicists look on the possibility with caution and even distrust". It is perhaps for that reason that he has devoted the greater part of his discussion to the physical evidence. While his diagnosis of the situation is, perhaps, not very inaccurate, it is scarcely a fundamental one. The reaction of the man of science—whether he be physicist or astronomer—to the idea will depend on his mental constitution. The passage from mathematical possibility to physical actuality is traversed much more easily in some minds than in others. Physicists have been known whose enthusiasm has sometimes triumphed over their scientific scepticism, and, on the other hand, even an astronomer may demand more than an æsthetic satisfaction in co-ordinating his observations. It would be a mistake to suppose either that the astronomer has a more elastic scientific conscience than the physicist or that the physical evidence for the annihilation of matter is less than the astronomical. The simple fact is that the hypothesis of the annihilation of matter is a legitimate, useful, and stimulating one, with at least as great a probability as any alternative that has been suggested, but that it awaits further observational and experimental data for its final assessment. In the meantime, we may be thankful that in these matters we have both pioneers and critics of the highest quality.

AT a meeting of the Council of the Royal College of Surgeons of England, held on July 9, Lord Moynihan was elected president, for the sixth year in succession. This constitutes a record in the annals of the College. Although an election to the presidential chair is made annually, it has become the custom to extend the office to three years. Only once before has this term been exceeded, when the late Sir William MacCormac was elected president five years in succession—1896–1901. During Lord Moynihan's presidency, research laboratories have been opened in connexion with the museum of the College, and research scholarships have been endowed to permit young men who intend to become surgeons to devote one year or more to experimental research. Research scholars are encouraged to maintain their connexion with their hospitals and to continue their participation in clinical work.

ON the eve of his re-election to the presidency of the College, Lord Moynihan laid the foundation-stone of an institute for surgical research—to be known as the Buckston Browne Farm for Surgical Research. The object of this farm is to permit the research students of the Royal College of Surgeons to carry out experiments on animals kept under the most favourable conditions. The erection and endowment of this invaluable addition to the equipment of the Royal College of Surgeons has been made possible by the munificence of one of its fellows, Mr. George Buckston Browne, who is giving £100,000 to the College in order that it may complete its scheme of research. Mr. Buckston Browne, as readers of NATURE will remember, purchased Down House, Charles Darwin's home for forty years, endowed it, and handed it over, with its grounds, 23 acres in extent, to the custody of the British Association. More recently, he bought 13 acres of land adjoining the western side of the Down House property and beautifully situated. This land he has conveyed to the Royal College of Surgeons, and it was a site on these new fields which was the scene of the ceremony in which Lord Moynihan played the leading part on July 8. In laying the foundation-stone, he said that owing to the great beneficence of a fellow of the College, they were laying the foundation-stone of an institute for experimental research which would add the one remaining link required for the proper development of surgery in Great Britain. The donor of the institute, in reply to Lord Moynihan, said that they had been able "to bring the great genius of John Hunter, who did so much to throw light on the living processes of the human body, alongside of the home of that other great genius, Charles Darwin, who did so much to emancipate the human mind from superstition. Both men are now brought together on a sacred spot in Kent." Mr. Buckston Browne's gift has been rightly described as the most beneficent ever made by a surgeon for the advancement of his profession.

To mark the occasion of its jubilee, the Society of Chemical Industry has issued a special number of *Chemistry and Industry* which will undoubtedly appeal to all who are interested in the historical aspect of applied chemistry. The earlier part of the issue is devoted to an account, not hitherto available in compact form, of the formation and development of the Society, which has been very closely identified with the growth of the chemical industry in Great Britain, and to an illustrated series of biographies of past presidents and medallists, amongst whom are numbered such distinguished men of science as Sir William Ramsay, Sir William Crookes, and Sir James Dewar. The second half of the volume, consisting of reprints of twenty-one of the more important papers which have been read before the Society during the past fifty years, indicates the wide range of topics which fall within the scope of the Society's activities. The reprints include the paper read by Sir Oliver Lodge before the Liverpool Section in 1886 on "The Electrical Deposition of Dust and Smoke, with Special Reference to the Collection of Dust and Fume, and to a Possible Purification of the Atmosphere"; Weldon's account of "Some Recent Improvements in Industrial Chemical Processes", read in 1882; Mr. William Macnab's fascinating story of "Some Achievements of Chemical Industry during the War in this Country and in France" (1922); and Sir William Pope's Royal Institution discourse on "Faraday as a Chemist" (1925). Apart from the event which its appearance commemorates, the issue is of importance on account of the great historical value of its contents.

THE Safety in Mines Research Board has issued its paper No. 66, being a report upon haulage accidents in collieries, and, as usual, the report is issued at the nominal price of 6*d.* so as to be available to all interested in colliery work. The subject is one of very great importance, first, because next to falls of ground, haulage accidents claim the largest number of victims in collieries, and in some districts are even the most prolific cause. Whereas it is quite true that the proportion of fatal to non-fatal accidents due to haulage is much less than that due to certain other causes, such as explosions of firedamp or coal dust, nevertheless, the very large number of non-fatal accidents show that the subject is one worthy of investigation. An interesting table in the report shows that whilst the number of fatal accidents per thousand persons employed has, roughly speaking, been halved since 1873, that due to haulage accidents is practically unchanged in that period, and this fact alone shows that the subject is worthy of serious investigation.

THE problem is a difficult one on account of the great variations, not only between different districts but also between different collieries in the same district. Thus, it is pointed out that there is a high rate of haulage accidents in Northumberland and Durham, and it is suggested that this may be due to the prevalence of bord-and-pillar working in this coalfield, involving a large use of pony haulage and of young lads in charge of the ponies. Again, it is pointed out that in one of the Scottish collieries the highest accident rate is nearly thirty times the lowest accident rate. The report naturally makes no definite recommendations as to what steps should be taken to decrease the number of accidents, that not being the object of the Committee; its work was simply to prepare a scheme for investigating possible methods of reducing the number of haulage accidents, and accordingly the Committee makes a number of recommendations for research, which appear to be thoroughly sound and well warranted by the conditions, although the Committee itself points out that many of these accidents "are due to causes which could only be overcome by a change in human nature".

THE small tortoise-house behind the old reptile-house—now converted into a bird-house—at the London Zoological Gardens has just been refitted as a tropical house; the atmosphere is most convincingly tropical, and one side is fitted up as a greenhouse-aviary, with stone-plants, rockwork, and a little streamlet and pool. Here are located a pair of African jacanas (*Actophilornis africanus*) and some interesting passerine birds, pittas, sunbirds, sugar-birds (Cœrebidæ), and small tanagers. On the other side there are three compartments, two tenanted by platyrhine monkeys, including a howler, and the third by the first hoatzin ever exhibited here. It is interesting to note that, just as the anatomy of this peculiar bird points to several different groups, so do some of its actions recall groups different again—it has the crouching walk and squatting pose on a perch of the cotton-teal or goslets (*Nettopus*) and the upthrow of the wings on alighting of the sandpipers. With the exhibition of this type the number of scientifically important bird-families yet to be exhibited is reduced to five—the todies, jacamars, puff-birds, finfoots, and the Mesitidæ of Madagascar. In the present reptile-house, an important acquisition is that of specimens of the Australian frilled lizard *Chlamydosaurus*, an agamid species so rare in captivity that it has only once been exhibited before. It has to rely for notoriety on its frill, its power of rearing and running on its hind-legs being now known to be shared by several other lizards, notably by the iguanid *Basiliscus*.

THE practice of shooting all abnormal varieties of birds is so prevalent that it is worth while to direct attention to a case recorded by Mr. M. Mason in the *Field* of June 20, in which a white hen grouse was protected instead. The result was that she lived to rear four broods, being at last found dead and torn in her fifth year. Of her offspring, many were pied and one cream-coloured, but no white was found in the second generation. Although it was suspected that her death was due to an eagle, her survival for so long may perhaps be attributed to the reduction in the number of predatory birds by modern game-preserving, but the fact that her offspring so soon lost any trace of her abnormal colouring indicates that other causes besides natural selection by enemies contribute to limit white colouring; it must also be remembered that though a brown protective plumage is so very common among game birds, and generally characterises the females even where the males are conspicuous, yet hens may be green, in *Rollulus*, and black in *Acomus*, while *Crossoptilum tibetanum*, a large, conspicuous bird, is nearly all white in both sexes and at all seasons.

CAPT. C. W. HUME has written protesting against our suggestion that truth had been sacrificed to propaganda in certain statements in "The Animal Year Book". Clearly he has not read our comments carefully, for although we gave page references to two particular statements, his reply omits to mention one and deals with another of which we made no mention and which is on neither of the pages quoted. But the kernel of the whole matter seems to us to be this. If cruelty is to be measured by the amount of suffering borne by the victim, the same punishment may have different cruelty values even in different men, for it will depend upon their sensitivity. Therefore the statement that the degree of pain suffered by a lower animal trapped by the leg is "roughly comparable to crucifixion" suffered by the much more highly organised and, moreover, self-conscious human being, is, to put it bluntly, rubbish. If, on the other hand, cruelty is to be measured by the intention of the torturer as well as by the suffering of the victim, the other statement we referred to is even less accurate, namely, that the torture inflicted by the steel-toothed trap and the common snare is on a par with the medieval torture of human beings. For, apart from the facts of comparative sensibility we have stated above, the deliberately designed tortures of human beings devised for the sole purpose of causing pain stand in a category by themselves. We do not wish to minimise the sufferings caused by steel traps; surely there is no need to exaggerate them.

MESSRS. Cooke, Troughton, and Simms have produced a simple instrument known as "The Orientator", for enabling architects, builders, house-agents, and others to determine visually from plans the direction in which the sun's rays will fall on any window, building, or wall during winter or summer. It consists of a flat metal ring, to the central end of a radius of which is attached a thread terminating in a small ball representing the sun. A portion of a second ring (which, if complete, would form a short

The Annihilation of Matter.*

By Sir JAMES JEANS, F.R.S.

THROUGHOUT the greater part of the history of science, matter was believed to be permanent, incapable either of annihilation or of creation. Yet a large amount of astronomical evidence now seems to point to the annihilation of matter as the only possible source of the energy radiated by the stars. A position has thus been reached in which the majority of astronomers think it probable that annihilation of matter constitutes one of the fundamental processes of the universe, while many, and perhaps most, physicists look on the possibility with caution and even distrust. I have thought it might be of interest to attempt a survey of the present situation in respect to this question.

THE ASTRONOMICAL EVIDENCE.

The astronomical argument for the annihilation of matter is based, not on the intensity of stellar radiation, but on its duration. No transformation of a less drastic nature than complete annihilation is found capable of providing continuous radiation for the immense periods of time throughout which the stars have, to all appearances, lived. For, with one conspicuous exception, to be discussed later, all available methods of estimating stellar ages are found to indicate that the stars, as a whole, have already lived through periods of millions of millions of years.

Some of these methods depend on the rate of gravitational interaction between adjacent stars, for example, the velocities with which the stars move through space show an approximation to equipartition of energy, such as must have required millions of millions of years for its establishment. The individual members of the groups of stars known as moving star clusters appear to have had their courses changed by the gravitational pull of passing stars to an extent which again indicates action extending over millions of millions of years. The same is true of the orbits of visual binary stars. In each of these three cases, the clock we use has for its unit a time analogous to what is called the 'time of relaxation' in the theory of gases; in this comparison the single stars correspond to monatomic molecules, and binary stars to diatomic molecules, while the disintegration of a moving star cluster provides the counterpart of the process of gaseous diffusion.

These estimates of stellar ages are, of course, valid only if we assume that the changes in stellar motions and arrangements are produced solely by the gravitational pulls of other stars. Other causes are conceivable, and must indeed contribute something—pressure of radiation, bombardment by stray matter in space, or by the atoms of cosmic clouds diffused through space. But calculation shows that the contributions from these sources are quite negligible. Indeed when we take them into account, the discussion of stellar movements is no longer a problem of astronomy, but of physics; we have to treat the stars as Brownian 'particles' in a physical medium. When they are so treated, we find that the starry medium has a temperature—in the sense in which we speak of the temperature of moving Brownian particles—of the order of 10^{62} degrees. Both individual and binary stars exhibit the equipartition of energy which corresponds to a temperature of this order, whence it is obvious that physical agencies such as pressure of radiation and atomic pressures, which are in equilibrium with far lower temperatures of the order only of 10^4 degrees, cannot have made any appreciable contributions to the establishment of this equipartition; they act as mere drags on the stellar motions, tending on the average to check their speed.

In a second class of binary stars, the spectroscopic binaries, the two components are so close together that the gravitational pull from passing stars is approximately the same on each, and so cannot exert the differential action which would change the relative orbits of the constituent masses. Clearly there can be no question of any approximation to equipartition of energy in the internal motions of these systems. Nevertheless, it is possible to trace a steady sequence of configurations, beginning with almost circular orbits in which the two constituents are practically in contact—this being probably the condition of a system which has just formed by fission—and proceeding to orbits which are far from circular in shape, in which the components are at a substantial distance apart. It seems likely, although not certain, that this sequence is one of advancing age; when the parent star first breaks up to form a binary, the newly formed system starts at the first-mentioned end and moves gradually along the sequence. Now observation shows, beyond all doubt, that the stars at the far end of this sequence are substantially less massive than those at the beginning. We know the rate at which the various types of stars are radiating their mass away in the form of radiation, and from this we can calculate the time needed to produce the difference of mass which is observed to exist between the two ends of the sequence; again it proves to be a matter of millions of millions of years. Here the clock we use is the rate of outflow of radiation from a star, or its equivalent, the rate of loss of mass.

---

* The substance of lectures delivered before the Universities of Princeton, Yale, and Harvard on May 23, 26, and 27 respectively, under the auspices of the Franklin Institute of Pennsylvania.

Against these various estimates must be set one piece of evidence which, if interpreted in the most obvious way, seems to point in exactly the opposite direction. This is, that the remote extra-galactic nebulæ all show a shift of their spectral lines to the red, the amount of shift being approximately, although not exactly, proportional to the distance of the nebula. If this is interpreted in the most direct way, as a Doppler effect, the nebulæ must all be scattering away from us and from one another in space, at so great a speed that the whole universe doubles its size about once in every 1400 million years. Such a rate of increase seems quite inconsistent with the estimate which assigns ages of millions of millions of years to the stars. Calculation suggests that the original radius of the universe must have been of the order of 1200 million light-years (Eddington), while the present radius of the universe appears to be only of the order of 2000 million light-years (de Sitter). If these estimates could be treated as exact, we could fix the age of the universe definitely at just more than 1000 million years, which is substantially less even than the age of the earth as indicated by its radioactive rocks. No one would claim any great degree of exactness for either of these estimates, especially the second, yet the general situation seems to forbid that the universe can have been doubling in size every 1400 million years throughout a period of millions of millions of years.

Although alternative interpretations are tenable, none of them seems entirely convincing, and the present situation is extremely puzzling. While there is obviously room for much difference of opinion, many astronomers consider it likely that some other explanation of the apparent recessions of the nebulæ will be found in time, in which event the road will be clear for the acceptance of ages of millions of millions of years for the stars, as suggested by the main bulk of astronomical evidence.

If such ages are provisionally accepted, calculation shows that the average star has already emitted many times its total mass in radiation; in other words, the average star must have started life with many times its present mass. Indeed, the sequence of spectroscopic binaries gives us a sort of picture of the life-history of a typical star. It starts with anything from ten to a hundred times the mass of the sun, and ends with a mass comparable to, or even less than, that of the sun. It is difficult to see where the enormous weight of the newly-born star can have been stored if not in the form of material atoms, or at any rate of material electrons and protons. Thus we are led to suppose that the life-history of the star is one of continual annihilation of its substance, the electrons and protons annihilating one another, and providing the energy for the star's radiation in so doing. Such, at least, is the conjecture suggested to us by astronomy; the testing of the conjecture rests with physics.

HIGHLY PENETRATING RADIATION.

If any direct evidence of this process of annihilation is to be obtained, it seems most likely that it will be found in the highly penetrating radiation which McLennan, Rutherford, and others discovered in the earth's atmosphere at the beginning of the present century. The reason, as we shall see later, is that here, and here alone in the whole of physics, we are dealing with photons of radiation whose mass is comparable with that to be expected in photons resulting from the annihilation of electrons and protons. In the last few years, this radiation has been studied in great detail by Hess, Millikan, Regener, and many others. Their investigations scarcely leave room for doubt that the radiation enters the earth's atmosphere from outer space: for which reason it is often described as 'cosmic radiation'.

It was at first taken for granted that this radiation must be of the nature of γ-radiation, since its penetrating power was greater than seemed possible for any kind of corpuscular radiation. This reason is now known to be inadequate, theoretical investigations having shown that corpuscular radiation, consisting of either α- or β-particles, might conceivably possess as high a penetrating power as the observed radiation.

Other arguments have, however, stepped into the breach, and show very convincingly that the radiation cannot be of the nature of either α or β radiation. The central fact is, in brief, that radiation which consisted of charged particles would be influenced by a magnetic field, whereas cosmic radiation is not. An electron or other charged particle in motion acquires magnetic properties in virtue of its motion; the faster it moves, the greater the force which a magnetic field exerts upon it. Now the penetrating power of the radiation under consideration is so great that it could only be attained by charged particles, if these were moving with very high speeds indeed. If a swarm of such particles became entangled in the earth's magnetic field, their high speed of motion would cause them to describe spiral paths coiled quite closely around the earth's lines of magnetic force, with the result that they would fall far more abundantly near the earth's magnetic poles than elsewhere. Epstein[1] estimates that for a shower of electrons to have the penetrating power of cosmic radiation, they would have to move with the energy produced by a fall through about 1000 million volts, and has calculated that the incidence of electrons moving with this energy would be limited entirely to comparatively small circles surrounding the two magnetic poles. Actually the observed radiation falls so evenly on the different parts of the earth's surface that no variations have ever been detected. Members of the B.A.N.Z. Antarctic Expedition[2] found the same intensity of radiation within 250 miles of the south magnetic pole as they had previously measured in South Australia, and as others had found in the United States, Canada, and the North Atlantic. This seems to leave little room for doubt that the radiation is of the nature of very hard γ radiation.[3]

At first, some experiments by Bothe and Kohlhörster seemed to throw doubt on this conclusion. They had placed two Geiger counters, one vertically above the other, and found that the number of coincident discharges in the two counters was just about that which would be expected from purely geometrical considerations, if the radiation was corpuscular. Of course, the radiation which produced these ionisations was not necessarily the primary radiation which fell on the earth from outer space. Any primary radiation, as it traverses the atmosphere, is bound to produce secondary radiation of a variety of kinds, and any one of these might have been the immediate cause of the ionisation observed by Bothe and Kohlhörster. The primary radiation which first enters the earth's atmosphere might quite conceivably be electromagnetic, while the ionisation might be produced by a secondary corpuscular radiation.

To examine this possibility, Bothe and Kohlhörster placed a block of gold between their two counters. This naturally caused a reduction in the number of coincidences, and from the amount of the reduction it was possible to calculate the penetrating power of the radiation which actually effected the ionisations. It was found to be approximately the same as that of the primary radiation. So far, then, everything could be explained by supposing that it was the primary radiation itself which produced the ionisations in the counters, and that this was corpuscular in its nature.

Recently this explanation has been tested by Moss-Smith[4] and found wanting. He extended the apparatus used by Bothe and Kohlhörster, by mounting yet a third counter vertically below the original two, and first verified that the number of coincident ionisations in all three counters was that which their geometrical arrangement would lead us to expect. Now if the radiation which produced these ionisations were corpuscular, it ought to be deflected by a magnetic field. For example, if a sufficiently strong magnetic field were inserted between the second and third counters, the third counter ought to be entirely shielded from the radiation which had passed through the first two counters, so that the number of coincident ionisations in the first two counters would remain as before, while the number in the third counter would fall to zero. Moss-Smith found that this did not happen. Although his magnetic field had many times the strength needed to shield the third counter completely, its insertion had no effect on the number of coincident ionisations. This showed that the ionising radiation was not corpuscular, and as Bothe and Kohlhörster had already shown that the ionising radiation was probably identical with the primary radiation, it confirmed the theoretical arguments of Millikan and Epstein, which proved the primary radiation to be of the nature of γ radiation.

THE MODE OF PRODUCTION OF THE RADIATION.

If the primary radiation is of the nature of γ radiation, as these arguments and experiments seem to show, its origin ought to be disclosed by its penetrating power. Such radiation consists of photons, which may be compared to bullets, all moving with the same speed—the velocity of light. Their penetrating power accordingly depends solely on their mass, and a theoretical investigation enables us to deduce the one from the other. Every photon is, however, produced originally by an atomic upheaval, and its mass is exactly equal to the decrease of mass which the parent atom experienced as the result of this upheaval. For example, if the atom was one of hydrogen and the upheaval consisted of annihilation, the photon resulting from this annihilation must have a mass exactly equal to the original mass of the hydrogen atom, namely, $1{\cdot}66 \times 10^{-24}$ gm. Or again, if a proton and an electron mutually annihilate one another in any atom whatever, thus reducing its atomic weight by unity, the mass of the resulting photon must be equal to the combined masses of the proton and electron in situ in the atom, which again, except for a small 'packing-fraction' mass, is equal to the mass of a hydrogen atom.

The most effective means of investigating the penetrating power of cosmic radiation is to sink suitable apparatus to varying depths below the surface of a lake, and observe the ionisation produced by the incidence of the cosmic rays after absorption by varying depths of water. Observations of this type have been performed with great care and skill by Millikan, Regener, and others.

Their results are none too easy of interpretation. L. H. Gray has shown [5] that there is a sort of softening effect continually in progress by which the absorption of a quantum of energy produces a recoil electron, which in turn produces radiation of energy comparable to, although somewhat lower than, the energy of the original quantum. After the radiation has travelled through a certain thickness of absorbing material, the observed ionisation no longer gives a true measure of the intensity of the primary radiation which has escaped absorption, but of this primary radiation in equilibrium with all its softer secondary components.

When this complication has been allowed for, the ionisation curve gives the intensity of the true primary radiation which remains after passing through varying thicknesses of absorbing matter. If this primary radiation consists of a mixture of constituents of different and clearly defined wavelengths, so that it has a line spectrum in the language of ordinary optics, these different constituents will have different coefficients of absorption. In such a case, it ought to be possible to analyse the observed curve into the superposition of a number of simple exponential curves, one for each constituent of the radiation.

Actually, it is found that this can be done. Different experimenters do not obtain results which are altogether accordant, but all agree in finding that there is a long stretch, near the end of the range of the radiation, over which its intensity decreases according to a simple exponential law. This can only mean that one particular constituent of the radiation is so much harder than the others that it persists in appreciable amount after traversing a thickness of matter which has completely absorbed all the softer constituents. Regener, who has studied the problem in great detail, finds that the hardest radiation of all has an absorption coefficient of 0·020 per metre of water. Other experimenters have found values which agree with this to within about 10 per cent.

The mass of the photon can be deduced from the observed absorption coefficient μ of the radiation, by the use of a theoretical formula given by Klein and Nishina.[6] This can be written in the form

$$\mu = \frac{2\pi N e^4}{m^2 c^4} f\left(\frac{M}{m}\right),$$

where M is the mass of the photon, m of an electron, e, c have their usual meanings, and f represents a fairly complicated function of M/m. In all the applications of the formula to cosmic radiation, M/m is quite large, and for such values of M/m, f assumes the form

$$f\left(\frac{M}{m}\right) = \tfrac{1}{4}\left(\frac{M}{m} + 2 \log \frac{2M}{m}\right).$$

These formulæ are calculated on the supposition that the absorption is caused by N electrons per unit volume, and that these are entirely free. This last condition can never be fully realised in Nature, since every electron is bound, more or less closely, to other electric charges. If an electron is bound to a system of mass m', we can allow for this binding by increasing m in the formula by a fraction of m', the fraction being large or small according as the coupling is tight or loose. Thus a loosely coupled electron behaves almost like a free electron, but an electron coupled tightly to a massive system, such, for example, as a proton or an atomic nucleus, behaves like an electron of very great mass, and the formula shows that this has no appreciable absorbing power.

The Klein-Nishina formula has been tested by comparing it with observation for γ-rays. In the case of the lighter elements, it gives values whch agree well with the observed absorption, provided all the extra-nuclear electrons are treated as free, while the nuclear electrons are disregarded entirely. It is natural to disregard these, because the coupling of nuclear electrons in the lighter elements is known to be so close that even the hardest γ-rays make but little impression on them. This is true for the lighter elements only; in the case of lead, Chao[7] has found an additional scattering of the hardest γ-rays, which he believes to be of nuclear origin. In other words, he finds that some at least of the nuclear electrons in lead are not so closely coupled as to resist the onslaught of the hardest γ-radiation. Still less, then, can they be so closely coupled as to resist the incidence of the far more massive photons of cosmic radiation. From theoretical considerations of a very general nature[8] it appears probable that in dealing with cosmic radiation, the *N* in the Klein-Nishina formula should refer to all electrons, nuclear as well as extra-nuclear, and not merely to the latter. A further term ought also to be added to represent scattering by nuclear protons, but calculation shows that this is entirely insignificant in amount. The result of taking the nuclear electrons into account is to replace atomic number by atomic weight, so that the absorption by a given thickness of matter becomes strictly proportional to the mass of the matter, and absolutely independent of its nature, except possibly in so far as a further small absorption, caused by photoelectric action, may depend on the latter. The effect of this is to double, or more than double, the capacity of all atoms except hydrogen for absorbing cosmic radiation; it increases the absorbing power of water to 80 per cent above the value usually calculated.

The following table shows the absorption coefficients (per metre of water) which I have calculated for the radiation produced by the synthesis of iron and by the annihilation of 1 and 4 protons respectively, with their accompanying electrons. The calculation is based on the Klein-Nishina formula, all electrons, including the nuclear electrons, being treated as absolutely free:

Process	$\frac{M}{m}$.	Calculated μ (per metre, water).	Observed μ (Regener).
$56H \longrightarrow Fe$	876	0·136	..
$+, - \longrightarrow 0$	1845	0·071	0 073
$4+, 4- \longrightarrow 0$	7380	0·020	0·020

The last column gives the absorption coefficients of the two most penetrating constituents of cosmic radiation, as analysed by Regener. Their agreement with the figures in the preceding column is probably well within errors of observation and analysis, and is rather too good to be attributed with much plausibility to mere accident; the odds against a double agreement, within 5 per cent in one case and 2·7 per cent in another, being about 3000 to 1. This seems to me to suggest quite strongly that the most penetrating constituent so far observed in cosmic radiation may originate in the annihilation of an α-particle and its two neutralising electrons (the components of a helium atom), while the next softer constituent may originate in the annihilation of a proton and its one neutralising electron (the components of a hydrogen atom).

An alternative possibility, which was first suggested by Millikan and has been championed mainly by him, is that the cosmic radiation may result from the building of electrons and protons into atoms. Yet the hardest constituents of the cosmic radiation appear to be far too hard to be produced by the synthesis of iron, while Millikan himself considers that the synthesis of heavier elements is probably ruled out by their rarity in the universe. If, as I have suggested, the annihilation of matter is the true origin of the two hardest constituents of the cosmic radiation, then it becomes possible to suppose, with Millikan, that the softer constituents are produced by the synthesis of simple atoms into complex. Many will, however, hesitate to accept such a mixed origin for the radiation. It certainly seems simpler to suppose that the two hardest constituents, and these alone, form the fundamental radiation, while all other constituents represent mere softened or degraded forms of these. Yet this supposition brings its own difficulties, since if we measure the intensity of the radiation by its ionising power, the supposed secondary radiation is found to have many times the ionising intensity of the primary. But whatever the origin of the softer constituents may be, the two hardest constituents, with their photons equal in mass to the atoms of hydrogen and helium respectively, appear to provide weighty evidence that matter can be, and is, annihilated somewhere out in the depths of space. If we can assume that this process occurs on a sufficiently large scale, this supposition brings order and intelligibility into a vast series of problems of astronomy and cosmogony in a way in which no other suppositions can.

THE PLACE OF PRODUCTION OF THE COSMIC RADIATION.

Various suggestions have been made as to the place of origin of this highly penetrating radiation. Many of them are put out of court by the fact, which must now, I think, be regarded as well established, that the radiation is nearly constant in intensity at all times of day and night,[9] any variation being, at most, of the order of one part in 200. There seems to be a real variation of this amount, but in the main it appears to follow the variation of the barometer: Millikan considers that it is adequately explained by fluctuations in the absorbing power of the air blanket formed by the earth's atmosphere. It was at one time suggested that the radiation might consist of electrons ejected from thunder-clouds high up in the earth's atmosphere, or of electrons moving with enormous speeds acquired by drifting through electrostatic fields in space, the potential gradients in these fields being slight, but the potential differences immense simply on account of the vast extent of the fields. Even if the radiation could still be treated as corpuscular, it would be very difficult to reconcile either of these suggested origins with the steadiness and uniformity with which the radiation falls on the earth's surface.

The fact that the intensity of the radiation is very approximately independent of both solar and sidereal time seems to show that no appreciable part of the radiation comes from the sun or stars. Counting the sun as a star, we receive more than 100,000,000 times as much starlight at midday as at midnight, yet apart from the purely local 'barometer' effect just mentioned, we receive the same intensity of the radiation at both times. The fact that the intensity is approximately independent of the position of the Milky Way seems to show that the bulk at least of the radiation must come even from beyond the confines of the galactic system, thus justifying the name 'cosmic radiation'.

Where, then, does the radiation originate? For reasons which will be clear at the end of our quest, it is simpler to conduct our search in time rather than in space. The average density of matter in space is probably of the order of 10^{-30} gm. per c.c., and in each second of its existence, a beam of cosmic radiation passes through a layer of space 3×10^{10} cm. thick. Thus every second it passes on the average through 3×10^{-20} gm. per sq. cm. of its cross-section. We have, however, seen that the hardest constituent must pass through 50 gm. per sq. cm. before it is reduced in intensity by one per cent, and this requires an average time of 16×10^{20} seconds, or about 5×10^{13} years—a period which, on any reckoning, is greater than the age of the stars; its intensity is reduced to $1/e$ times its original value after 5×10^{15} years, which is greater, so far as we know, than the age of the universe.

Thus, to an approximation, we may think of the hardest constituent of the cosmic radiation as indestructible, since the universe has not yet existed long enough for any appreciable amount of it to be absorbed. To a slightly less good approximation, the same is true of the softer constituents. This leads us to regard space as being permeated with all, or nearly all, of the cosmic radiation which has ever been generated since the world began. The rays come to us as messengers, not only from the farthest depths of space, but also from the remotest eras of time. And, since we cannot produce cosmic rays on earth, their message appears to be that the physics which prevails out in these far depths of space and time is something different from our terrestrial physics: different processes result in different products. So far as we can read the riddle of the rays, one at least of these processes appears to be the annihilation of matter, although whether this annihilation is taking place now, or occurred only in the remote past, or even only at the beginning of the world's history, we have no means of knowing; all that the rays show is that somewhere and sometime in the history of the universe, matter has been annihilated.

Similar remarks may be made with respect to the softer constituents. Millikan believes that these originate in the synthesis of complex atoms out of lighter ones, and so argues that the act of creation is still in progress. But these softer constituents also have such high penetrating powers as to be virtually indestructible. Even if Millikan's interpretation of the origin of these rays were established, it would only prove that synthesis of matter had occurred somewhere and sometime during the long past history of the universe; it would not prove that any such synthesis was still in progress.

Indeed, the fact that the radiation does not vary in intensity with the position of the Milky Way may be thought to suggest that it is merely a relic of past eras in the history of the universe. It may be argued that if the radiation were still being generated, the huge mass of the Milky Way, comparatively close to our doors, would surely make its influence felt. It is, however, possible (and, I think, likely) that the radiation is still being generated in extra-galactic nebulæ of earlier type than the galactic system; it may be that they only emit this radiation before they condense into stars; and that the atoms which can produce such radiation in the galactic system are all shut up inside the stars, so that the radiation is transformed into starlight before it reaches us.

Millikan has estimated that the total amount of cosmic radiation received on earth has about a tenth of the energy of starlight, sunlight not being counted in. Near the earth, the energy of radiation from the stars is intense enough to raise space to a temperature of about 3·5 degrees absolute, whereas the energy of cosmic radiation will raise this space only to about 2 degrees absolute. Out in the inter-galactic darkness the position is reversed. Here the feeble starlight and star-heat from distant galaxies can at most raise space to a fraction of a degree above absolute zero, but the intensity of cosmic radiation is probably the same as nearer home, corresponding to about 2 degrees absolute. Space as a whole appears likely to contain far more of cosmic radiation than of light and heat, although in assessing this fact, we must remember that cosmic radiation is virtually endowed with immortality, whereas ordinary radiation, in the form of light and heat, is not. The total annihilation of all the matter in the universe would raise space to about 10 degrees absolute, so that the cosmic radiation we observe could be produced by the annihilation of quite a small fraction of the universe.

This is not surprising, since the cosmic radiation which pervades space is necessarily quite distinct from the similar radiation which astronomers regard as the source of stellar light and heat. The annihilation of matter in stellar interiors would produce radiation of exactly the same high frequency as the observed cosmic radiation, but as this radiation fought its way outwards to lower temperatures, and finally to outer space, it would be continually softened, by a long succession of Compton encounters, until it finally emerged in the familiar form of starlight—ordinary temperature radiation at anything from 1650° abs. to about 60,000° abs.; none of it could reach the earth in its original form.

The mere fact of its not having been completely absorbed shows that the cosmic radiation we receive on earth cannot have passed through more than a few kilometres of stellar matter at most; its penetrating power, high though it is, will not carry it through a greater thickness of matter than this. Consequently, it can scarcely have been generated at a place where the temperature was more than about 100,000 degrees. We must suppose that it originated fairly near to the surfaces of astronomical bodies, or, more probably still, in unattached atoms or molecules in free space. In contrast to this, the radiation which provides the energy poured out by the stars was probably generated in their central regions. Thus it must have been generated in matter at very high temperatures, while the similar radiation we receive on earth must have been generated at comparatively low temperatures.

PHYSICAL PRINCIPLES.

According to classical theories of electro-magnetism, any acceleration of a moving electron is accompanied by an emission of radiation, of amount given by the well-known formula of Larmor. Thus an electron, describing an orbit in an atom of, say, hydrogen, must continually radiate energy away, so that the orbit will continually shrink.

The quantum theory replaces this continuous emission of energy by a succession of discontinuous emissions; at each moment there is a definite calculable chance that the orbit will shrink in size by a finite amount, and emit a photon in the process. The orbit of lowest energy is anomalous; when an electron is describing this orbit, no further shrinkage in orbit or emission of radiation is possible.

The concept of annihilation of matter removes this anomaly by providing a state of still lower energy, in which proton and electron have both disappeared in radiation. The energy emitted in the process of annihilation corresponds, of course, to that which would be emitted continuously on the classical electro-dynamics while the orbit was shrinking to zero radius.

Although neither the new quantum theory nor the theory of wave mechanics in any way predicts that this process must actually happen, they are in no way definitely antagonistic to its occurrence. Certain forms of both, on the whole, seem rather to favour the possibility, but theoretical calculation based on these does not at present agree with numerical estimates derived from astronomical evidence. Dirac[10] has recently calculated the probability of annihilation given by the new quantum theory, and obtained a value which is substantially too large; according to his calculations, the universe ought to have dissolved into radiation long ago. Or, to put the same thing in another way, the stars ought to radiate energy far more furiously than they do.

The general principles of the quantum theory show that annihilation of matter might either occur spontaneously, after the manner of radioactive disintegration, or might be incited by a sufficiently high temperature, like the atomic changes which produce ordinary temperature radiation. The second process will only occur when the matter is traversed by photons with energy equal to that set free by annihilation of matter; the requisite temperature is found to be of the order of a million million degrees. Now it is quite impossible that the cosmic radiation we receive on earth can have originated in regions where the temperature approaches this; indeed, we have seen that it can scarcely have been more than 100,000° or so. Thus this radiation can only have originated from spontaneous annihilation. Cosmic radiation can, and very possibly does, provide evidence of the spontaneous annihilation of matter at low temperatures, but it cannot, from the nature of the case, give any evidence of annihilation being produced by high temperatures, since any radiation so produced could never get out to empty space.

There seem to me to be two strong reasons for supposing that this latter process is not operative in the stars, and that any radiation which is produced by annihilation inside the stars must be produced spontaneously, like the cosmic radiation which is produced outside.

In the first place, if the generation is not spontaneous, the temperature at the star's centre must be of the order of a million million degrees. An immensely steep temperature gradient would be needed to connect this temperature with that of a few thousand degrees at the surface of the star, and so steep a gradient can only be reconciled with the observed flow of heat out of the star by postulating a very high opacity for the stellar material. It has so far proved impossible to reconcile such a high value for the opacity with the theoretical value given by Kramers.

The second reason is as follows. If the generation of energy results from high temperature, the rate of generation will involve a factor of the usual type $e^{-Mc^2/RT}$, where M is the mass annihilated. As the temperature increases from zero up, this factor first becomes appreciable when RT begins to be appreciable in comparison with Mc^2. This happens at the temperature of about a million million degrees already mentioned. When this temperature is first approached, the exponential term is increasing very rapidly in comparison with the temperature T. But a dynamical investigation shows that when this happens, the star must be very unstable. In brief, the emission of appreciable radiation would be accompanied by instability in the star, so that the very stable structures we describe as stars cannot radiate by means of this mechanism. The dynamical result has, it is true, been rigorously proved only for a simple, and very idealised, model of stellar structure; but general thermodynamical principles show that any structure in which a small change of physical conditions results in a very great liberation of heat, is likely to be unstable—in brief, it is in an explosive state.

On the other side, there is one strong argument against supposing that stellar radiation is produced by spontaneous annihilation of matter; it is that if the sun's heat were produced by the spontaneous annihilation of its atoms, we might expect that the earth's atoms would be subject to spontaneous annihilation at an equal or similar rate. Yet calculation shows that annihilation at even a ten-thousandth part of this rate would make the earth too hot for human habitation. Clearly, then, no appreciable annihilation of matter can occur inside the earth. This must be formed of atoms of a kind which do not undergo spontaneous annihilation, and if the sun derives its heat from the spontaneous annihilation of atoms, these must be of a different kind from the atoms of which our earth is formed. This is not in itself unreasonable; from the mode of the earth's formation, its atoms can be a sample only of those in the sun's outer layers. If we conjecture that those kinds of atoms which undergo spontaneous annihilation are of very great atomic weight, and so sink to the interiors of the stars, this difficulty disappears, and with it the problem of why no cosmic radiation is received directly from the Milky Way.

cylinder) is fixed to it at such an inclination that if the first ring is horizontal the edges of the second follow respectively the paths of the sun in the sky at the summer and winter solstices. Any one instrument is, of course, suitable only for a single latitude. The instrument is placed on the plan with the centre of the horizontal ring over the window or wall in question and with an appropriately marked point in the north direction, and the thread is stretched by holding the ball between the fingers. When the thread rests against an edge of the inclined ring (on which a scale is engraved giving the hours of the day) its direction is therefore that of the sun's rays at the corresponding solstice. Observation of the plan from above then shows immediately what obstacles to sunlight, if any, are encountered. The makers point out that since the declination of the sun changes only slowly near the solstices, the instrument is trustworthy for a considerable portion of the year; but an obvious improvement would seem to be the provision of slits in the inclined ring, through which the thread could pass to represent the sun's rays at intermediate times. The instrument can be supplied for any latitude, north or south. It weighs 1 lb. and is 6 in. in diameter at the base. It is constructed of stout brass, which is chromium-plated to resist corrosion and to prevent soiling of the plans. The cost is £2 2*s*.

An international festival of folk-dancing is to be held in Copenhagen on July 25, when representative teams from all Scandinavian countries, including Finland, Greenland, and the Faroe Islands, will attend. An English team of members of the English Folk-Dance Society will also take part. The festival should be of the greatest æsthetic and scientific interest, especially as some of the dances—those from the Faroes, for example—must be of considerable antiquity, and in certain cases suggest, almost unquestionably, an ancestry to be traced ultimately to a form of sun worship. Folk-dancing is becoming increasingly international, and thus, when the dances of different countries are seen side by side, affords exceptional opportunities for the comparative study of survivals of primitive custom and belief. For example, in the year-book entitled "In Northern Europe 1930", edited by Mr. Rolf Gardiner, there are accounts of expeditions to East Prussia, Silesia, and the Baltic towns, as well as a description of the English tour of the German singers, when they were accompanied by English dancers. Further, the English Folk-Dance Society is arranging to visit Paris for a demonstration on July 25 in the British Music Society's English week at the Colonial Exhibition, and it is hoped to bring Transylvanian dancers to England next January. An endeavour is also being made to organise an international festival on a large scale, to be held in London in 1936.

A notable advance in naval machinery has been made in the destroyer H.M.S. *Acheron*, of which some particulars are given in an illustrated article in the *Engineer* for June 26. The *Acheron* is one of the 'Acasta' class, being 312 ft. long and of 1330 tons displacement, but whereas the *Acasta* and other vessels have a working steam pressure of 300 lb. per sq. in., the steam pressure in the *Acheron* is 500 lb., with a total steam temperature of 750° F. instead of 600° F. The engines have been built by the Parsons Marine Steam Turbine Co., Ltd., and the hull and boilers by Messrs. J. I. Thornycroft and Co., Ltd. In the *Acheron* there are two sets of turbines, each consisting of one high pressure, two intermediate, and one low pressure turbine, and one astern turbine coupled to the shaft through double-reduction gearing. The designed shaft horse power is about 34,000. The three boilers are of the three-drum Thornycroft type, the drums being of forged steel, machined inside and outside, while the solid-drawn steel tubes are $1\frac{3}{4}$ in. in diameter. Superheaters and pre-airheaters are fitted. In an exhaustive series of trials, the oil consumption at full power was 0·608 lb. per shaft horse power per hour, while the water consumption was 7·77 lb. per shaft horse power per hour. At ten per cent full power, the oil consumption per shaft horse power per hour was 0·92 lb. and the water consumption 12·87 lb.

Thanks to the generosity of S. and H. Behn, the house in which A. M. Ampère, the great French physicist, spent his boyhood and youth has been presented to the French Society of Electricians. The house is situated at Polémieux-les-Mont-d'Or, about nine miles north of Lyons. The society has published an account of the ceremonies that took place on the occasion when they took possession of the house and fixed a plaque at the entrance commemorating the name of Ampère. Speeches were made by well-known physicists and engineers, and Paul Janet gave an interesting account of the life and work of the great physicist. Born in 1775, his youth was spent in troublous times. In 1793, when he was only eighteen years of age, his father was executed on the scaffold—a victim of the Revolution. Ampère's work on the mathematical theory of electricity has been of the greatest help to physicists and engineers. He died at Marseilles in 1836, but in 1869 his remains were transferred to Montmartre Cemetery. The name of ampere has been universally adopted for the practical unit of electric current.

The fifth triennial meeting of the General Assembly of the International Research Council was held at Brussels on Saturday, July 11, when the new statutes were approved and adopted. By these the name of the organisation is changed to that of the 'International Council of Scientific Unions', and full liberty is left to the International Unions to develop their activities in the way best suited to each. Dr. George Hale was elected president in succession to M. Picard, who has retired. The other members of the new executive committee are: General G. Ferrié and Prof. U. E. Norlund, vice-presidents; Dr. P. Pelseneer and Prof. F. A. F. C. Went, members; and Sir Henry Lyons, general secretary.

The Human Betterment Foundation (Pasadena, California) has issued a pamphlet on "Human Sterilisation". It is pointed out that eugenic sterilisation, by means of vasectomy in the male and salpingectomy in the female, carries no stigma or humiliation and does not unsex the individual in any way except in making parenthood impossible. Twenty-five States in the Union now have sterilisation laws on their statute books, and some six thousand operations of this nature have been performed. Following up the cases, it was found that six patients out of seven were satisfied with the operations. Many feeble-minded girls have married after sterilisation and these marriages have been reasonably successful in the great majority of cases. Whereas three-fourths of these girls were sex delinquents before sterilisation, only one in twelve has been a sex offender since. This is good evidence that sterilisation will not increase delinquency when it is made part of a well-organised system of probation and parole. The conditions and safeguards under which sterilisation is performed in Californian institutions are described.

THE following appointments have recently been made by the Secretary of State for the Colonies: Mr. J. De Verteuil, agricultural chemist, Trinidad, to be agronomist, Trinidad; Mr. A. J. W. Hornby, agricultural chemist, Nyasaland, to be assistant director of agriculture, Nyasaland; Mr. W. T. O. Maidment, assistant superintendent of agriculture, Gold Coast, to be agricultural officer, Uganda.

DR. E. C. S. DICKSON, of the Department of Physics, University of Manchester, has written pointing out that the demonstration of the Thomson effect described by Mr. W. Band in NATURE of June 27, p. 975, will also be found in Geiger and Scheel's "Handbuch der Physik", vol. 1, p. 330 (1926), in a large collection of lecture experiments that does not appear to be so well known as it deserves.

THE Swiss Society of Natural Sciences will hold its 112th annual session at La Chaux-de-Fonds and Le Locle on Sept. 24–27, under the presidency of Dr. C. Borel. On the first day, Prof. A. Piccard will give a lecture on his recent ascent into the upper atmosphere in a sealed car attached to a balloon, and Dr. C. Perret will exhibit a film on the life of bees. On Sept. 27, there will be two lectures. The first will be given by Prof. P. Arbenz on the geological history of South Africa and its camp sites, and the second by Prof. Pérez on rhizocephalods parasitic on hermit crabs. Several excursions to places of interest have been arranged in connexion with the meeting. The secretary of the meeting is M. A. Vuille, Numa Droz, La Chaux-de-Fonds.

A DETAILED programme has now been issued for the International Illumination Congress, which is to be held in Great Britain on Sept. 1–19. Provision is made for visits to London, Glasgow, Edinburgh, Sheffield, Buxton, and Birmingham, following which the sessions of the International Commission on Illumination will be held at Cambridge. An item of outstanding interest in the London programme is the proposed trip to the Port of London, returning to the Tower of London and Westminster by river, so that the illuminated buildings on the riverside may be seen. Throughout the visits to the cities named, the technical sessions, at which more than a hundred papers will be presented, will alternate with agreeable trips and social events. During the proceedings at Cambridge a lecture will be given by Sir Arthur Eddington. Membership of the Congress is open to anyone interested in illumination on payment of a registration fee of £2. Those desiring to take part in the Congress should communicate with the honorary general secretary (Col. C. H. S. Evans, 32 Victoria Street, London, S.W.1) without delay.

THE Medical Supply Association, Gray's Inn Road, W.C.1, has issued a catalogue (T.L. 20) of new models of X-ray apparatus and appliances, and electric wax-baths. Ultra-violet light fluorescence cabinets are listed. These consist of a chamber housing a quartz mercury vapour lamp, the rays from which pass through a window of 'filter' glass which screens off the visible or luminous part of the radiation and allows only the ultra-violet or invisible radiation to pass. By this means the fluorescence of various substances may be observed, such as fats, drugs, papers, precious stones, chemicals. It may also be employed for the detection of forged notes, fraudulent erasures, etc., as well as for the examination of certain skin diseases.

THE Ministerio de Agricultura of the Argentine Republic has published a well-illustrated and instructive pamphlet on the commercial breeding of rabbits for the market—"Explotación del Conejo en la Argentina" (1931, 75 pp.). It deals fully with the best methods of housing, feeding, and tending generally the breeds of chinchilla, angora, castorrex, and others, which have become popular in recent years. But, as a furrier expressed it recently to the present writer, you may call the fur what fine name you will, it remains rabbits' fur none the less, with all the weaknesses to which rabbits' fur is heir, from the furrier's point of view.

IN view of the rarity of the book and of its importance to students of the Mollusca, a facsimile reprint of those parts of the "Beschreibung der Naturalien-Sammlung der Universität zu Rostock" by H. F. Link, 1806–8, which refer to Mollusca, is being prepared for issue on Oct. 1. The edition is limited to 150. Copies may be obtained on application to Mr. J. R. le B. Tomlin, 23 Boscobel Road, St. Leonards-by-Sea, Sussex, or to Mr. R. Winckworth, 71 Whitworth Road, London, S.E.25, who are preparing the reprint. The price will be £1 or 5 dollars, post free. Advance subscribers may receive a copy at 15*s*. or 3.75 dollars, post free.

PART 6, fascicle 2, of "Diptera of Patagonia and South Chile", has been published by the British Museum (Natural History). It comprises the families Phoridæ (supplement), by A. Schmitz; Platypezidæ and Pipunculidæ, by J. E. Collin; Sphæroceridæ, by O. W. Richards; and Eplydridæ, by E. T. Cresson, jun. Four new genera and a number of new species are described in detail, the descriptions being accompanied by ten text-figures and a half-tone plate.

THE co-operation of the school child in the matter of personal and general hygiene can only be positively achieved by a simple communication of the outstanding facts about health and disease. For classwork, the series of thirteen coloured health and hygiene charts recently produced by Messrs. G. Philip and Son, Ltd., will be found a help; they have been produced with the aid of Dr. Winslow, of Yale University. A descriptive booklet for the teacher is appropriately written by Prof. V. H. Mottram.

Two 43-page pamphlets record additions made to the Hull Museums. The additions are of many kinds, but records of ancient forms of travel and of the slave trade, and relics of the old-time whaling, for which Hull was famous, predominate. Many of the specimens are illustrated, and are described or commented upon in readable paragraphs, which have been reprinted from the *Hull Daily Mail*. The descriptive paragraphs are to be commended as affording more matter of interest to the general reader, and therefore better museum publicity, than the bare lists of the names of objects which some museums serve up in the daily newspapers.

THE Director of the Peabody Museum of Natural History, Yale University, Dr. R. S. Lull, and the Trustees are to be congratulated upon the excellence of the "Special Guides" to the collections which have just been issued. The first two numbers, the forerunners, we trust, of a longer series, have been written by Dr. Lull to explain "The Evolution of the Horse Family" and "The Evolution of the Elephants and Mastodons". They are simply written, clearly paragraphed, well illustrated, and sell at the modest price of 15 cents (31 and 40 pages respectively). Such pamphlets should do more than blatant propaganda for the spread of knowledge of evolution in the United States.

AN exhibition of publications of the League of Nations opened on July 14 at the Old Court House of Messrs. J. and E. Bumpus, 350 Oxford Street, W.1. The publications of the League, the International Labour Office, and the World Court will be simultaneously on view. During the ten years of its existence the League has already published some 3000 documents and periodicals, and last year alone more than 1,500,000 copies were printed, numbering over 61,000 pages. More than six hundred publications will be exhibited, with historical documents, maps, photographs, etc., and also the latest and most important books relating to the origin, work, and history of the League. During the exhibition, which will be open for a month, short lectures will be given by experts at 3.30 P.M. on Mondays, Wednesdays, and Fridays.

MESSRS. Baillière, Tindall and Cox are publishing shortly for the Bentham Trustees the "International Address Book of Botanists" which has resulted from the resolution of the fifth International Botanical Congress, 1930. This will be on lines somewhat similar to Dorfler's "Botaniker Adressbuch", and will contain the names of 13,000–14,000 botanists and botanical institutions, etc., in all parts of the world. These will be arranged alphabetically by countries, printed in the majority of cases in the language of the country, and provided with an index of personal entries and geographical indices. The low price of 12*s.* 6*d.*, or 13*s.* post free, is rendered possible owing to the assistance the International Committee has received from the Bentham Trustees and the Carnegie Corporation of New York.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant pathologist at the Swansea General and Eye Hospital—The Secretary-Superintendent, General and Eye Hospital, Swansea (July 20). Teachers of science and technical subjects and of woodwork, metalwork, and technical drawing, at the Chelmsford Mining and Technical Institute, Dinnington, Yorkshire—A. Rayner, 151 Cross-hill, Ecclesfield, near Sheffield (July 21). A laboratory attendant and storekeeper in the chemistry department of the University of Leeds—The Registrar, University, Leeds (July 24). A demonstrator in the engineering test laboratory and the physics laboratory of the Royal Naval Engineering College, Keyham—The Adviser on Education, Admiralty, Whitehall, S.W.1 (July 27). A full-time lecturer in zoology at the Chelsea Polytechnic—The Principal, Chelsea Polytechnic, Manresa Road, S.W.3 (July 29). A lecturer in architecture at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (July 31). A demonstrator in chemistry in the University of Aberdeen—The Secretary, University, Aberdeen (Aug. 15). A head of the Department of Entomology of the Rothamsted Experimental Station—The Secretary, Rothamsted Experimental Station, Harpenden (Sept. 11). Assistant keepers in some or all of the departments of zoology, entomology, geology, mineralogy, and botany of the British Museum (Natural History)—The Director, British Museum (Natural History), Cromwell Road, S.W.7. A technical assistant for calculation and experimental work in connexion with aero engine investigations under the Directorate of Technical Development of the Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants. A technical assistant for experimental metallurgical work under the Directorate of Technical Development of the Air Ministry—No. A. 502, The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants. A lecturer on elementary electrical engineering, for evening classes at the Borough Polytechnic—The Principal, Borough Polytechnic, S.E.1. An assistant master for mathematics and elementary science at the Cambridge and County School of Arts, Crafts, and Technology—The Education Secretary, County Hall, Cambridge. A junior demonstrator in physiology at the University of Durham College of Medicine—The Registrar, College of Medicine, Newcastle-upon-Tyne. A Clothworkers scholar for research in the physical properties of wool and other fibres in the University of Leeds—The Clerk to the Senate, University, Leeds.

ERRATUM.—In the article entitled "Modern Whaling" in NATURE of July 11, p. 56, line 17, for "1925" read "1905".

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Excitation Potentials of Metallic Lithium.

A LARGE amount of work has been published on the excitation potentials of metals (the so-called excitation of soft X-rays). On account of the very great complexity, no precise correlation has been achieved between these experiments and the results of the theory of metal structure. But—especially in view of the scarcity of spectroscopic data on metals—it would seem that there should be, concealed in these results, information of fundamental importance for the theory of metals, if only we knew how to use them. The chief essential for any such use is to attain the utmost possible simplification, and thus, just as the theory of atoms was built up from results on hydrogen, one is led to the study of the excitation potentials of metallic lithium.

It happened that no experimental data on lithium metal exist. Experiments were therefore undertaken. The method used was similar to that of Richardson, with some refinements. The lithium metal was distilled on to a copper anode at a suitably high temperature to prevent so far as possible the condensation of impurities. The radiation from the lithium falls on a copper sphere and the photoelectric current which results is measured by an accurate balance method. Thus one can plot the intensity of the radiation from the lithium, as measured by the photoelectric current, against the voltage of the electrons producing it. A sudden increase in slope in this curve at a definite voltage indicates an excitation potential of metallic lithium.

The photoelectric current was found to start with a voltage of 6 volts. A further break was found at 9 volts. Then the curve runs quite smoothly, and finally almost linearly to 51·5 volts, where there is a very large break, in which the slope is immediately about doubled. A further smaller break occurs at 57·5 volts. Then again the curve runs quite smoothly and no breaks whatever are found so far as has been investigated (up to 400 volts).

Lithium metal consists of a lattice of nuclei each with two K-electrons; the outer electrons of the lithium atoms combine together to form the set of conduction states of the metal, which are known to have a voltage range of the order of 10 volts. It seems fairly safe to assume that the lower breaks obtained correspond to transitions among the conduction electron states.

There remains the K-radiation of the lithium metal, and one is forced to associate this with the breaks at 51·5 and 57·5 volts. By applying a voltage correction of the order of 2 volts, we may allow for the acceleration of the exciting electrons in passing through the surface field of the lattice and state that the minimum excitation potential for the K-radiation of lithium metal is about 53·5 volts.

On the analogy of ordinary hard X-rays, one might picture the excitation process as follows. An electron is ejected from a K-level either through the crystal surface or into one of the upper conduction levels, the deeper conduction levels being assumed to be filled up. The latter process requires the minimum energy. Then an electron may drop back into the empty K-level from any conduction level with the emission of radiation. Thus we might expect a K-spectrum extending over about 10 volts below the critical point; and since probably the emission process involving the least energy would be the most likely, we might suppose that the greatest intensity in the spectrum would be concentrated at the low energy end of the spectrum.

Some experiments on the velocity analysis of the photoelectrons, ejected from the copper by the radiation excited in the lithium by 300-volt electrons, did not confirm this picture. Though rendered slightly inconclusive by the considerable 'loss of velocity' effects which occur in the energy range of the lithium K-radiation, they indicated that the maximum intensity in the K-spectrum is concentrated near the excitation point, namely, at about 53 volts, and there appears to be some radiation up to 60 volts energy, though none beyond.

However this may be, an apparent difficulty certainly arises when we compare the value 53·5 volts of the critical potential with the value of the K-ionisation potential of the lithium atom which has been accurately calculated by Braunbek.[1] The value is 64·6 volts and thus there is a discrepancy of 11 volts to be accounted for. Any attempt to explain it as a perturbation of the K-level due to close packing is out of the question, as it would lead to the spontaneous explosion of the metal.

The low value obtained was therefore surprising and has led to great care being taken in the experiments to verify the result. The fact that the photoelectric current is always proportional to the primary current to the lithium shows that the observed excitation potential corresponds to a single process excitation.

To interpret the result, we must suppose that there are empty levels into which the K-electron can be transferred at the base of the conduction electron system, so that the K-electron does not have to be taken through the energy levels of the conduction electron system, but can stay in a level at the base of the conduction electron levels. In the unexcited state all such levels are certainly filled. But when a K-electron is removed, the state of affairs becomes radically changed owing to the altered screening of the nuclear charge. I am greatly indebted to Prof. Bohr for pointing out that this altered screening will in itself create new levels round an atom in the lithium lattice which will not be filled. The new levels will correspond to a smaller total energy than the normal conduction electron levels. Thus the K-electron can be excited into one of these new levels and a *resonance* radiation will be emitted just as would be the case with free atoms. This process, of course, does not preclude the excitation of K-radiation by ionisation.

We may add that experiments in progress with beryllium metal, though the results are not so simple as with lithium, lead to similar conclusions.

Evidence for the Spin of the Photon from Light-Scattering.

IT is well known that in the encounters between molecules and photons, exchanges of energy occur which are rendered evident by the observed changes in frequency of the scattered light. Whenever in such an encounter a molecule gains or loses spin-energy, there is a corresponding change in its angular momentum, which can only be explained on the assumption that there is an equal and opposite change in the spin-moment of the photon. This involves definite consequences for the state of polarisation of the scattered light, and opens up the possibility of demonstrating experimentally the existence of angular momentum in radiation.

The general principle involved is sufficiently illustrated by considering the case of a photon which is circularly polarised and is scattered without change of direction by a molecule the axis of spin of which coincides with the axis of circular polarisation. If the spin of the molecule is unaffected by the encounter, the scattered photon retains its original character. On the other hand, if the molecule gains two additional units of angular momentum, the photon will alter in frequency and at the same time *change over from right-handed to left-handed circular polarisation* or vice versa. The considerations are naturally not so simple in the general case in which the molecule is arbitrarily orientated and the photon is scattered in a direction not coinciding with the primary ray. It may be shown that besides the reversal of the sign of circular polarisation in the forward direction, there would also result a depolarisation of the scattered light, which would be specially evident in directions transverse to the primary rays.

It may be remarked that similar phenomena should also be observed when, as the result of an encounter with the photon, a change in spin-energy of the molecule is superimposed on a change in its vibrational state. On the other hand, a change in vibrational state alone would not give rise to the effects indicated.

It may be noted that certain interesting observations recently reported by Hanle and by Bär[1] find a natural explanation in the considerations set out above. In support of the view that the scattered radiations exhibiting strong depolarisation or reversal of circular polarisation involve rotational transitions, it may be mentioned that the lines exhibiting such effects are usually diffuse, while lines which are well polarised are usually sharp and intense.

Absolute Rates of Heterogeneous Gas Reactions.

FOR a decomposition reaction catalysed by a surface, in which the catalysis depends upon the formation of an adsorption complex (in adsorption equilibrium with the gas phase) and subsequent thermal activation and break-up of the complex into new molecular species which then evaporate, simple analogy with the theory of homogeneous reactions leads to an expression for the rate: $K = f.n.e^{-E/RT}$, where K is the number of molecules reacting per sq. cm. per second, n is the number adsorbed per sq. cm., f is frequency with which an adsorption complex undergoes a change in its total energy content (analogous to collision frequency for a homogeneous reaction), and $e^{-E/RT}$ is an approximate expression for the chance that after any particular energy change the complex is left with energy exceeding E. E is a quantity specific for the complex and not merely for the reaction.

When the complex in question consists of some simple molecule (NH_3, N_2O, HI) attached to the catalyst surface atoms, then every molecule may be supposed to decompose, at least so far that the completion of the act is inevitable, within an interval less than $1/f$ after activation; a reasonable value for the order of magnitude of f is clearly that of atomic vibration frequencies, here taken as 10^{12}.

The application of this is limited to surfaces of known area and uniform activity for the reaction in question. The catalysts which come nearest to fulfilling this condition are smooth metallic surfaces (for example, drawn metal wires). As a practical criterion, when the reaction can be shown to have a constant activation energy over a hundred- or thousand-fold velocity range, there is strong presumption that all parts of the surface which catalyse the reaction at all are uniformly active. The following calculations have been made for reactions on heated wire catalysts where catalyst poisoning by the products is demonstrably absent.

Kinetically zero order reactions: Here n is taken as the number of molecules in a close-packed layer, and E is equal to the Arrhenius constant A.

Reaction.	K. Exp	K. Calc.
NH_3 decomposition on tungsten.[1] $A=38700$ $T=904°$	4×10^{17}	4×10^{17}
NH_3 decomposition on tungsten.[2] $A=41500$ $T=1316°$	2×10^{19}	13×10^{19}
NH_3 decomposition on molybdenum.[3] $A=53200$ $T=1228°$	$5\text{-}20 \times 10^{18}$	2×10^{18}
Dissociation of Pt(CO) complex.[4] $A=31800$ $T=650°$	4×10^{16}	2×10^{16}

There seems to be no reason why the atomic vibration frequency factor should not be applied to the desorption of adsorbed molecules attached by a definite linkage to the surface atoms; to reactions in which the de-sorbed molecule carries with it an atom of the metal; to reactions in which the solid grows at the expense of the adsorbed molecules with which it reacts, as in the deposition of nickel from the carbonyl.

Kinetically first order reactions: It has been pointed out that the Arrhenius constant now requires a correction equal to the heat of desorption.[5] But this may be extended to take into account the absolute magnitude of n as a function of p and T, by means of the Boltzmann e-law for the density of molecules in a region of potential energy L, identifying this region with a layer extending for one molecular diameter (taken as 3×10^{-8} cm.) from the surface. The expression appropriate to the linear adsorption underlying the first order kinetics comes out to

$$n = p_{\text{bars}} \cdot e^{\frac{L}{RT}} \cdot \left\{\frac{2{\cdot}2 \times 10^{8}}{T}\right\}.$$

Then $$K = f \cdot p_{\text{bars}} \left\{\frac{2{\cdot}2 \times 10^{8}}{T}\right\} e^{\frac{L-E}{RT}}$$

and $$\left(\frac{d \log_e K}{dT}\right)_p \times \frac{A}{RT^2} = \frac{E-L}{RT^2} - \frac{1}{T},$$

so that $$K = p_{\text{bars}} \cdot f \cdot \left\{\frac{2{\cdot}2 \times 10^{8}}{T}\right\} e^{-\left(\frac{A+RT}{RT}\right)}.$$

(In hot wire experiments at very low pressures the gas phase concentration round the wire would not vary as $1/T$; the RT term in the energy of activation drops out, and T in the term in curl brackets must be taken as the temperature of the gas phase.)

The use of the Boltzmann expression when the adsorbed molecule has potential energy of vibration relative to the surface, being in fact held to the surface in virtue of just this potential energy, is not strictly justified, but should give the order of magnitude of n

correctly. The important thing is that if n can be calculated in this way it is not necessary to know E and L separately.

Reaction.	K/p_{bars}. Exp.	K/p_{bars}. Calc.
HI decomposition on platinum.[6] $A = 13800 \quad T = 836°$	6×10^{12}	22×10^{12}
N_2O decomposition on gold.[7] $A = 29000 \quad T = 1211°$	4×10^{11}	4×10^{11}

The agreement in all these cases is probably good enough to be significant. The zero order HI decomposition on gold [8] provides a clear-cut exception, the rate being 5×10^4 times greater than the calculated rate of activation. The difficulty of accounting for a *greater* rate suggests that the reversibility of this reaction, in the adsorbed layer before the iodine diffuses away, is the reason—this could have the effect of increasing the apparent value of E.

It should be interesting to repeat this calculation on other suitable catalytic reactions when the material becomes available.

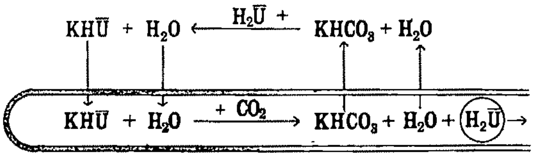
Excretion of Uric Acid.

A study of the excretory system of the blood-sucking bug, *Rhodnius prolixus*, has led to the formulation of the following theory of uric acid excretion in that insect:



It is supposed that the upper parts of the four Malpighian tubes secrete a solution of acid urates from the blood into the lumen, and that in the lower parts water and base are re-absorbed, leading to a precipitation of the insoluble uric acid. Thus there is a continuous circulation both of water and of base.

The evidence on which this theory is founded is, briefly, as follows: (1) There are striking histological differences between the upper two-thirds and the lower third of the tube, and uratic granules are confined to the lower third. (2) Neutral red and other vital dyes are taken up from the blood by the cells of the upper segment, and from the lumen of the tube by the cells of the lower segment. (3) Ligation of the tubes at various levels shows that uric acid (or urate) is secreted by the upper segment, and that there is no secretion into the lumen in the lower segment. (4) From 80 to 90 per cent of the uric acid in the urine is not combined with base. (5) Free uric acid is so insoluble that, if it were being excreted in saturated solution in the upper segment, and water re-absorbed in the lower segment, the four Malpighian tubes of this insect (which is 2 cm. long) would have to deal with 20 c.c. of fluid per diem in order to eliminate the daily output. By the mechanism indicated above, they would have to deal with only 0·4 c.c. per diem. (6) The contents of the tubes are faintly alkaline (pH 7·2) in the upper segment, definitely acid (pH 6·6) in the lower segment. A saturated solution of uric acid is about pH 6·5.

A full account of this work will be published shortly; but the object of this letter is to direct attention to the possibility of the same mechanism being employed in the elimination of uric acid by reptiles and birds. The probability of a circulation of water through the excretory system of these animals has long been recognised, and the possibility of a circulation of base is suggested by the following data. Uric acid is present in the blood in the form of urates. In the urine of the snake, Kohler [1] found that 83 per cent of the uric acid was free; and in the urine of hens 90 per cent is free.[2] Therefore, if all the uric acid is derived from a glomerular filtrate, base must have been re-absorbed. On the other hand, if the uric acid is secreted in solution by the tubules, since acid urates of sodium and potassium are from thirty to sixty times as soluble as free uric acid (at least in pure water), the suggested mechanism would afford a substantial economy of work.

It would be interesting to know if there is other evidence for this mechanism.

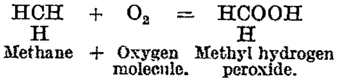
The Peroxidation of Hydrocarbons during Combustion in Air.

Prof. Bone has quoted in his letters with regard to the mechanism of combustion several interesting experimental results which he considers confirm the hydroxylation theory. He has recently directed attention to the finding by Dr. D. M. Newitt and Mr. A. E. Haffner of methyl alcohol in the oxidation products of methane and states that this has "shown conclusively that the slow oxidation of methane proceeds throughout in accordance with the hydroxylation theory".[1]

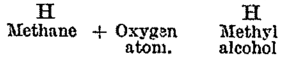
The presence of methyl alcohol in the oxidation products of methane can, however, be explained with equal success by the Engler-Bach peroxidation theory of combustion (1897) recently developed by Callendar and Mardles, Moureu and co-workers, and others (1926). According to the peroxide theory of combustion, the primary reaction is the formation of a moloxide or activated peroxide which catalyses the gaseous reaction and is responsible for autocatalysis and autoxidation.

Callendar and Mardles pointed out [2] that with paraffin hydrocarbons alkyl hydrogen peroxides might be formed by the simple inclusion of the oxygen molecule in a CH grouping, as, for example, in the following equation with methane:



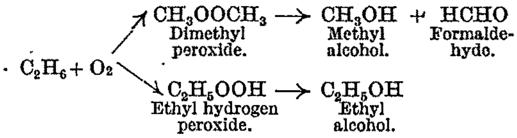
$$\underset{\text{Methane}}{\overset{\text{H}}{\underset{\text{H}}{\text{HCH}}}} + \underset{\substack{\text{Oxygen}\\\text{molecule.}}}{O_2} = \underset{\substack{\text{Methyl hydrogen}\\\text{peroxide.}}}{\overset{\text{H}}{\underset{\text{H}}{\text{HCOOH}}}}$$

It will be observed that in the formation of methyl hydrogen peroxide there is no atomic separation in the oxygen molecule as is required by the hydroxylation hypothesis



$$\underset{\text{Methane}}{\overset{\text{H}}{\underset{\text{H}}{\text{HCH}}}} + \underset{\substack{\text{Oxygen}\\\text{atom.}}}{O} = \underset{\substack{\text{Methyl}\\\text{alcohol}}}{\overset{\text{H}}{\underset{\text{H}}{\text{HCOH}}}}$$

The molecular disruption of the primary peroxide results in the formation of alcohols, esters, glycols, acids, aldehydes, hydrogen, etc. Rieche and Hitz[3] have shown that methyl alcohol can be formed from methyl hydrogen peroxide by decomposition. Similarly, alcohols are formed by the decomposition of ethyl hydrogen peroxide or dimethyl peroxide.[4] These peroxides are formed primarily from ethane during slow combustion according to the Callendar and Mardles hypothesis, namely:



$$C_2H_6 + O_2 \rightarrow CH_3OOCH_3 \text{ (Dimethyl peroxide)} \rightarrow CH_3OH \text{ (Methyl alcohol)} + HCHO \text{ (Formaldehyde)}$$

$$C_2H_6 + O_2 \rightarrow C_2H_5OOH \text{ (Ethyl hydrogen peroxide)} \rightarrow C_2H_5OH \text{ (Ethyl alcohol)}$$

It is interesting to note that methane is unique amongst the paraffin hydrocarbons in having a very low temperature coefficient of gaseous reaction, especially with rich mixtures. This rather suggests that autoxidation by the moloxide occurs to an important extent.

Velocity of Sound in Tubes: Ultrasonic Method.

FOLLOWING the experiments of Boyle and Froman,[1] further work has been done on the velocity of sound in liquids contained in tubes, and the experimental observations now appear to be satisfactorily explained.

A theoretical investigation shows that the frequencies, at which selective absorption of the longitudinal wave occurs, correspond to those of the resonant radial vibrations in the column of liquid. The radial frequencies are principally dependent upon the diameter of the containing tube and the properties of the liquid, the material and thickness of the tube wall being of much less importance. The selective absorption is caused by the energy of the longitudinal vibration being converted into a radial vibration. At the absorbing frequency the longitudinal wave is scarcely propagated at all, and the radial oscillation is very strong.

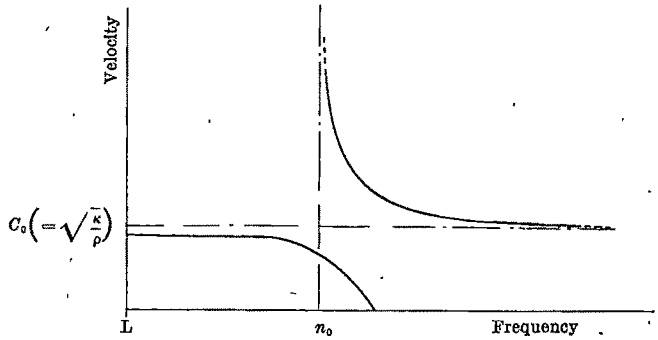

FIG. 1.

The theoretical curve (Fig. 1), which agrees well with experiment, indicates that for a range of frequencies just above the absorbing frequency (n_0) the velocity tends to have two different values, one high and the other low. This explains the experimental difficulty, noted by Boyle and Froman, in obtaining good stationary waves in this region.

The double-velocity effect is due to the fact that the wave-form below the absorbing frequency is different from what it is above, and the low-frequency type of vibration tends to persist slightly beyond the critical frequency. It may be remarked that in the absorbing region the wave is far from plane, but it becomes more and more so as the frequency becomes more removed from this region.

That there are two distinct types of vibration, one before and the other after the resonant radial frequency, has been experimentally verified by measuring the particle velocities for both cases with a Rayleigh disc.

Absorption of the longitudinal wave has also been measured and found to occur not only at the fundamental radial frequency but also at harmonics of it, the experimental and calculated frequencies agreeing very well.

It is to be noted that, following the usual procedure for sound, velocity has been plotted against frequency, whereas in optics (compare curves showing selective absorption) it is customary to plot refractive indices against wave-lengths. The optical method is rather illogical, because changes in refractive index mean changes in velocity and hence in wave-length; it is the frequency which is not affected by the absorbing medium. What is really plotted in optics is the refractive index (corresponding to λ_0/λ) against λ_0, where λ_0 is the wave-length that *would* have obtained if there had been no absorption. Velocity (actual) against frequency (actual) appears to be a much better method of expressing the facts.

Complete papers, covering the theoretical and experimental work outlined above, are shortly to be published elsewhere.

[1] NATURE, Oct. 18, 1930.

Control of Prickly Pear by the Cochineal Insect.

THE note in NATURE of June 27, p. 989, on the eradication of prickly pear in South Africa suggested that information about the use of *Dactylopius tomentosus* in the tropics might be of interest. The insects were imported by me into South India by courtesy of the Ceylon Government entomologist.

The object was to destroy clumps of *O. dillenii* in which dangerous snakes were harbouring around business premises. The insects would therefore be called, rather quaintly, in Australia 'private cochineal'.

The commencement of attack by a colony is very slow. For about two months in a shady clump, or perhaps twice as long in an exposed clump, no effects are generally visible. A few weeks after the attacks become visible the insects have overtaken the vegetable growth, and this is symptomised by heroic efforts of the plant to produce fruit; collapse quickly follows, and the insects then appear to concentrate upon producing winged males. It almost seems as if this were a consequence of starvation or the changed composition of the decaying juices. A good sign of the extreme selectiveness of the *D. tomentosus* is the fact that grass and weeds spring up untouched immediately a cactus clump collapses. Further evidence of this habit was also obtained when the *D. indicus* destroyed *O. monacantha* without touching the adjacent *O. dillenii*, in South India.

Indian farmers applied to me for infected stems, and cleared many thousands of acres simply by throwing these into objectionable clumps. Official attitude was not enthusiastic, but tolerant; European unofficial opinion was nervous; in fact, conditions were exactly as described in the Australian official papers before the Australian Government had decided to encourage private efforts.

Provided that no enemy (such as the Australian beetle) is found in Africa, it will be advantageous to employ biological control, because it introduces no poisons into the soil, and in the long run it enables a specified amount of labour to deal with the maximum area. For very intensive action, it might pay to cut tracks through dense areas by chemical means to facilitate broadcasting of the insects.

Glemham, Harpenden Road,
St. Albans, June 28.

The late Sir Francis Ogilvie.

Sir Francis Grant Ogilvie, who died last December, was Principal of the Heriot-Watt College from 1886 to 1900, taking office when the fortunes of the Watt Institution and School of Arts were merged with those of George Heriot's Hospital.

The work which Sir Francis did was of a pioneer character in the College and he laid down the lines which have since been successfully developed. He touched other fields of activity in each of which his scientific knowledge and administrative genius were of great service. In the Royal Scottish Museum, of which he was director from 1900 to 1903, as principal assistant secretary for Science and Art in the Board of Education from 1903 to 1910, as director of the Science Museum, South Kensington, from 1911 to 1920, and as chairman of the Geological Survey, he left his mark on each branch of activity. His work in organising the Forth Division Submarine Miners from 1887 to 1900, and in the Trench Warfare Research Department, 1915 to 1917, gives an indication of the wide range of his interests and the usefulness of his services.

It has been thought desirable by a number of old students that Sir Francis Ogilvie's connexion with the College should be recognised in some definite way. The suggestion of a fund to establish an annual prize has found favour, and I have received donations towards such a fund from a number of old students and members of the College, and from former colleagues and friends of Sir Francis. There are, no doubt, others who would wish to be associated with this memorial fund, and I should be glad to receive and acknowledge any contributions which they might wish to make. In this way the name of the first principal will be definitely brought before future students year by year.

J. Cameron Smail.

Heriot-Watt College,
Edinburgh, June 29.

Alchemical Apparatus.

My colleague Prof. Earp has directed my attention to an article in the *Journal of Hellenic Studies* (vol. 1, p. 109; 1930) by F. S. Taylor, entitled "A Survey of Greek Alchemy", in which the suggestion is made that the apparatus called a 'water bath' (bain-marie) by Berthelot ("Introduction à l'étude de la chimie des anciens", Paris, 1889, p. 146) is really a small charcoal brazier. I had already explained this point in some lectures given three or four years ago in connexion with the course in the history, principles, and method of science in the University of London, and it is quite clearly stated in my book, "Everyday Chemistry" (Macmillan, 1929, p. 68), published in the year preceding Mr. Taylor's paper. The use of the apparatus in the operation of *kerotakis* is connected with the practice of encaustic painting, in which the four colours, black, white, yellow, and red, were (according to Pliny) the first to be used. These four colours are very important in the theories of Demokritos of Abdera, and reappear in an alchemical sense in the traditions ascribed to Demokritos in the earlier treatises, in which the process of transmutation is closely related to painting and dyeing.

J. R. Partington.

Mile End Road, E.1.

Forestry Research in Great Britain.

Mr. J. Ramsbottom in a letter in Nature of June 20, p. 927, states that little or nothing has been done in Britain concerning investigations on tree mycorrhiza, and that no one has been wholly engaged in its study. Mr. Ramsbottom has overlooked the fact that Dr. M. C. Rayner has been engaged whole-heartedly on these problems for several years, having previously given much attention to the mycorrhiza of other plants. At the Johannesburg meeting of the British Association in 1929, a research committee was appointed to facilitate Dr. M. C. Rayner's whole-time researches on "Mycorrhiza in Relation to Forestry", and this Committee was reappointed in 1930. Valuable results have been obtained in these investigations, which will be published in due course.

F. T. Brooks
(Chairman, British Association
Research Committee on
Mycorrhiza in Relation to Forestry).

Botany School, Cambridge.

The Editor of Nature has kindly submitted the above letter to me for any comment I may care to make upon it. The object of my letter was to direct attention to the need of greater opportunities for research, which by taking a wider view of the interrelations of different organisms will benefit forestry in the only way which will count with practical men. I took into account the work mentioned by Mr. Brooks, with other investigations which are in progress. In so far as one investigator is 'whole time' (though not in the sense I meant), the necessary small correction may easily be made in my previous letter.

J. Ramsbottom.

British Museum (Natural History),
Cromwell Road, London, S.W.7.

The London Skull.

I have read with particular interest Prof. Elliot Smith's remarks on the 'Lady of Lloyds'' skull in the review entitled "Human Palæontology".[1] When he first described this skull in 1925, I pointed out[2] that on stratigraphical grounds I considered the Terrace in which the skull was found to be that on the surface of which Mousterian working floors have been found at many localities, and that I had shown the Terrace as such (that is, Middle or Taplow Terrace) on the Geological Survey maps. There was, however, some discrepancy between this view, based mainly on the mapping of the deposits, and that of the palæontologists, who assigned the Central London deposits to a post-Mousterian date. When making the geological survey of the area I considered this view and concluded that it was based on grounds insufficient to outweigh the stratigraphy. It is therefore highly satisfactory to me to find that in Prof. Elliot Smith's weighty opinion the human palæontology confirms my decision.

C. N. Bromehead.

Research Items.

Cult of the Sacred Bull in Ancient Egypt.—Mr. O. H. Myers contributes to *Discovery* for July an account of the past season's excavations carried out by the Egypt Exploration Society in the Bucheum, or burial-place of the sacred bull, at Armant, near Luxor. The Baqaria, or burial-place of the mothers of Buchis, near by, was also excavated. The Bucheum was functioning from the thirtieth dynasty to the time of Diocletian. Numerous stelæ in the Bucheum, some in situ, make it possible to assign most of the bulls to the ruler who inducted them, and in the Baqaria the evidence from a variety of sources, in conjunction with that from the Bucheum, enables the mothers of many of the sacred bulls to be identified. The Bucheum is roughly T-shaped, the base of the T being the entrance to a sloping ramp. Many tombs are situated half-way down this ramp; but the greater number are along the cross passage. In accordance with Egyptian idiosyncrasy, the earlier tombs are well-made solid sarcophagi cut from one stone and well spaced, but they degenerate through a stage of well-built sarcophagi of neatly dressed blocks to badly dressed blocks and finally to burials in the passage itself. A series of stelæ ranging from the time of Darius III. to Diocletian alleges a personal interest in Buchis on the part of the rulers, including the Roman emperors, and it is stated with doubtful credibility that Cleopatra VI. herself brought the bull up the river from Karnak for his induction. The site has proved disappointing in the matter of the objects found. A Nemes vase in green faience inscribed "Beloved of Osiris Buchis the King Nekht-Hor-Heb" and a fine group of bronzes, including two inscribed situlæ and a Kebeh vase, and stone and faience amulets are the most notable. A good corpus of pottery has been constructed.

Spermicidal Power of Chemical Contraceptives.—Effective birth control by means of chemical contraceptive agents must depend upon their spermicidal power and their mode of application, and such agents must be non-toxic and non-irritating, at least in the concentrations employed. The spermicidal power of chemical contraceptives upon guinea-pig sperms has been the subject of an investigation by Mr. J. R. Baker on behalf of the Birth Control Investigation Committee (see *Jour. Hyg.*, vol. 31, No. 2, April 1931, p. 189). Full details of the technique employed are given, and some comparative experiments indicated that guinea-pig sperms seem to react to spermicides much in the same way as human ones. The killing concentration of 36 substances was determined, this being defined as the lowest concentration in the series 2, 1, 1/2, 1/4 per cent, etc., which suffices to kill every guinea-pig sperm suspended in a special glucose-saline solution (simple saline is unsuitable) in half an hour at body temperature in four consecutive experiments, and the following figures are the killing concentrations per cent. Mercuric chloride and formaldehyde were the most active, 1/256; hexyl resorcinol, 1/64; soaps, 1/32; potassium permanganate, 1/16, and phenol, 1/2. Acetic and lactic acids, 1/32, and citric acid, 1/16; it is the concentration of hydrogen ions which determines the activity of acids. Some of the commonly used contraceptives are relatively inactive; thus, quinine hydrochloride and sulphate, and chinosol, only act at 1/2, while boric acid, magnesium sulphate, and alcohol fail to kill at 2 per cent. Certain very poisonous substances, such as potassium cyanide, prussic acid, and strychnine hydrochloride, have very slight spermicidal power, and active disinfectants are not necessarily good spermicides. Foaming mixtures containing tartaric acid and sodium bicarbonate, as in effervescing pessaries, seem to be active without the addition of a spermicide, and could probably be used alone as contraceptives. Details are given of the structure of the guinea-pig sperm and of the effect of changes in osmotic pressure upon it. Spermicides generally act upon the acrosome in the head of the sperm, and it either becomes shrunken and distorted or swells and bursts. The characters for an ideal chemical contraceptive are formulated.

Air-pressures upon a Bird's Wing.—A very remarkable photograph of a Montagu's Harrier about to land at its nest is reproduced in *British Birds* (June 1931): The upper wing-coverts are ruffled up as if by a breeze blowing from the rear of the bird. Lieut. R. R. Graham, in a short article discussing the photograph, supplements his earlier descriptions of the part played by the feather-arrangements in the wing in regulating air-pressures upon the wing (*British Birds*, June and July 1930). The wing is in a 'stalled' condition, held flat against the air-stream, with the result that eddies of air swirling round the hind margin into a region of reduced pressure, have actually blown up the feathers from behind. The photograph also shows the tips of the primary feathers separated, so that they form a 'slotted' device, comparable to the Handley-Page slot in aeroplanes, which adds greatly to the efficiency of the wing-tips by smoothing out the air-stream passing over the fore margin of the wing.

Transformation of Scales in Goldfish.—In order to discover what changes take place in scales transplanted from any part of the body to the lateral line, Yasumasa Mori has carried out a series of experiments upon goldfish (*Jour. Fac. Sci. Imp. Univ. Tokyo*, Sect. 4, vol. 2, p. 185; 1931). Lateral line scales were pulled out, and in their places scales from an area outside the lateral line were inserted. It was found that the transplanted scale becomes a lateral line scale, acquiring all the organs of the lateral line, a bony sheath, a sense organ in the lumen, a nerve regenerated from the torn stump of a branch of the lateral nerve, blood-vessels, and a pore penetrating the scale. The growth of the new structures generally commences beneath the pore of the preceding scale, and where a series has been transplanted the anterior individual acquires the new organs much more rapidly than those posterior to it. The whole process of transformation generally takes about two months, but in very rapid cases complete transformation has been observed in one month.

Symbiosis of Fungus and Scale Insect.—The relations between the fungus *Septobasidium retiforme* and the scale insect *Aspidiotus osborni* are discussed by J. N. Couch (*Quart. Jour. Micr. Sci.*, vol. 74, pt. 3, 1931). The fungus forms flat patches on the bark of oak and other trees in North Carolina and is entirely superficial, never penetrating the tissues of the tree. Such patches provide a home and protection for the scale insects, which suck the juices of the host plant, grow, and finally reproduce their young in vast numbers. These young may settle down beneath the same fungus under which they were born and repeat the cycle, or they may crawl out to other fungus-insect colonies, or settle on clean bark. These last are responsible for the dissemination of the fungus. Some of the young become infected with the fungus soon after they are born, the infecting fungal cell or cells entering the circulatory system and there developing numerous coils which absorb food from the insect. A number of the insects are finally killed and used up by the fungus; others, though infected, may digest the fungal haustoria and survive to reproduce. While the fungus within the insect's body has been developing, the hyphal threads which make up the fungal floor of one of the patches have more or less overgrown and covered the insect's body. As soon as the insect moults the second time the fungal threads which have grown over its body from the floor pass under the moulted skin, and coiled hyphæ from within the insect's body anastomose with the hyphæ outside. Thus a colony of *Septobasidium* is not descended from a single spore but is composed of many strains. The thick roof of fungus affords protection to the scale insects against extremes of temperature, against drying and the attacks of parasitic hymenoptera. The association of fungus and insect is regarded as symbiotic.

Oranges and Arsenates.—The chemical changes observable in ripening oranges during the last hundred days of their growth have recently been studied in some detail by Copeman (*Trans. Roy. Soc. S. Africa*, **19**, 107; 1931). Particular attention has been paid to the contrast between normal oranges and those from trees which had been sprayed with lead arsenate to combat the attacks of insect pests. The general results agree in showing an increase in soluble solids in the juice during ripening, and this includes nitrogen, ash, and also sugars. Of the latter, sucrose, glucose, and fructose appear to be in equilibrium during this stage of development, since their relative proportions remain constant although the total amounts increase. Acidity, however, progressively decreases, and this decline is much more marked in fruits from trees receiving arsenate sprays. The oranges from sprayed trees thus have a characteristically insipid flavour owing to their low acid content. The effect is considered to be due chiefly to an intensification of respiration produced by arsenates; and since the effects of arsenates are metabolic in character, variations in the mode of application of the spray are not likely to remove the deleterious effects. New methods of combating insect pests in citrus culture must therefore be sought.

The Origin of Acid Igneous Rocks.—The problem of the association of acid and basic rocks (for example, granite with gabbro and rhyolite with basalt) is discussed from a new point of view by Prof. A. Holmes in the *Geol. Mag.*, June 1931. It is pointed out that inside the oceanic province bounded by the circum-Pacific belt, granites and rhyolites are totally lacking, and that these rocks are produced only where pre-existing acid rocks occur of the types that characterise the continental blocks. The distribution of the cone-sheets of such British Tertiary centres as Mull and Ardnamurchan makes it clear that the magmatic reservoirs from which they were fed rose to within three miles of the surface; that is to say, the reservoirs invaded the granite shell through a thickness of four or five miles. Consideration of the problem of what happened to the granitic material that previously occupied the place of the reservoirs leads to the conclusion that it became fused in situ. A source for the necessary heat is found in the upward transfer of heat by convection currents within the deeper basaltic portion of each reservoir. It is shown, by comparing the thermal gradient maintained by convection with that expressing the rise of fusion point with depth, that temperatures well above the fusion point can be reached in the upper part of a reservoir, thus providing an excess of heat, which becomes available for fusing the rock-material of the bounding walls and roof. It is also pointed out that the operation of convection is fatal to the possibility of deriving a granitic differentiate from a parental basaltic magma, though it is not denied that in appropriate circumstances, where convection does not operate, such differentiation may be locally achieved.

Fluctuations in Cosmic Radiation.—It has been reported at various times that the intensity of the cosmic radiation is not constant, but that it depends upon meteorological and extra-terrestrial conditions. A discussion of a number of the supposed fluctuations, based partly upon new measurements of high accuracy made by himself by an ionisation method, is given by G. Hoffmann in the issue of the *Zeitschrift fur Physik* for June 13. There appear to be definitely at least two distinct influences of major importance, one being effective with the more penetrating components of the radiation, and the other with the weaker components, which are cut off by putting a relatively thin shield over the apparatus. With the harder rays, there is a pronounced inverse dependence upon the barometric height; when the graphs for the intensity of this radiation and the barometric pressure are plotted suitably on the same time base, one is closely the mirror image of the other. Presumably it is a question of absorption of radiation of extra-terrestrial origin in the atmosphere, although, as Millikan has pointed out, the dependence upon pressure also involves the temperature of the air. For the more easily absorbed rays, the new measurements of Hoffmann show a variation with the temperature of the air; their intensity increases with increase in temperature, a fluctuation of about ten per cent of the total ionisation going with a change in temperature of ten degrees. This could possibly be connected with movement of emanation and radioactive material in the air, but no correlation between the amount of the soft radiation and the direction or strength of the wind was found. Hoffmann remarks that the problem of establishing unambiguously a dependence of the intensity of the radiation upon sidereal time is a very difficult one.

Propagation of Electromagnetic Waves.—Interesting speculations as to the laws governing the propagation of wireless waves are given by Prof. H. Nagaoka of Tokyo in a paper published by the Institute of Physical and Chemical Research, No. 297 (April 1931, Tokyo). He points out that the presence of a highly ionised layer in the upper atmosphere—the Kennelly-Heaviside layer—has for a long time been assumed as a working hypothesis to explain the phenomena of transmission. It is now generally believed to consist of two or even three layers at different heights. It merely indicates that the number of free electrons varies at different heights in the atmosphere. The reflection of the waves at the bounding surface between gases is not so sharp as that between solids. The wave path turns round sharply, passing through an apex. He proves that at the apex where the wave begins to bend downwards the electron density is proportional to the square of the frequency. The density of electrons varies with the altitude of the sun, and is therefore a function of the latitude as well as of the solar declination. If observations were made for a year in different stations scattered over the world, the nature of the distribution of electrons in the upper atmosphere could be determined. The problem calls for international co-operation. To explain the presence of silent zones in short-wave transmission it is necessary to assume two conducting layers. The electron density which determines the wave-path varies for several reasons. The number of electrons coming from the sun and reaching the earth's atmosphere is much affected by the number of sunspots, by auroral displays, and magnetic storms. The day and night variation can be satisfactorily explained, but sunrise and sunset fading needs further study. Auroræ are a great hindrance to wireless working, as they produce sudden and violent changes in electron density. Meteoric showers have a much smaller effect. Reasons are given for supposing that helium plays an important part in forming conducting layers. There are many natural gas springs in America that have been emitting helium for countless generations.

Production of High Vacua.—For many years certain materials have been used in lamps and vacuum tubes for removal of traces of gas, these being known as 'getters'. Two classes of getters are in use: (i) Those acting as adsorbents (active charcoal, copper oxide, thoria, etc.), (ii) those having great chemical activity (alkali metals, alkaline earth metals, phosphorus). Phosphorus is generally used in lamps. In the May number of the *Journal of the American Chemical Society*, Andrews and Bacon describe comparative experiments on the efficiencies of calcium, barium, magnesium, sodium, and phosphorus, deposited as thin coatings on the walls of bulbs or tubes, from the point of view of the attainment of vacuum. They report pressures of about 10^{-7} mm., the lowest measured pressure yet reached by other workers in the laboratory (of the General Electric Company) being less than 5×10^{-9} mm. in a gauge connected with a large tube of well degassed charcoal immersed in liquid air. The main result of the present experiments was that differences in the previous treatment of the getters are of far greater importance in the removal of gas than differences among the getters themselves. Poorly degassed materials absorb residual gas slowly and reach equilibrium at higher pressures than those attained by more gas-free material. These pressures do not depend on temperature in the range 0°-90°.

The Oxidation of Iodide by Persulphate.—A study of the velocity of oxidation of iodide by persulphate ion, described by King and Jacobs in the May number of the *Journal of the American Chemical Society*, is of interest both from the point of view of experimental technique and the Brönsted theory of reaction velocities as correlated with the Debye-Hückel theory of ion activity. Instead of titrating the iodine liberated, the authors added a small amount of thiosulphate and determined the time of first appearance of iodine by a photoelectric cell circuit with a long absorption cell of solution. This permitted the use of very dilute solutions, to which alone the theoretical equation could be expected to apply. Agreement with a linear curve of the logarithm of the velocity constant plotted against the square root of the ionic strength, as required by theory, was found up to the value 0·06 of the abscissa. Above this, there was an increasing negative deviation. When the ionic strength is made up largely of univalent ions, the best straight line extrapolates to log $k_0 = -1{\cdot}075$, whilst with a large proportion of bivalent ions it extrapolated to $-1{\cdot}06$. The difference is considered to be significant, though small, and it may be due to the inaccuracy of the Debye-Hückel equation for bivalent and tervalent ions, even in very dilute solutions. This deviation has been previously found, and can be qualitatively explained.

Astronomical Topics.

Tree-Rings and the Sunspot Cycle.—The researches of Dr. A. E. Douglass on the correlation between the growth-rings in trees and the sunspot cycle have given a probable sunspot curve for many centuries. A *Science News Bulletin* issued by Science Service, Washington, D.C., dated June 23 announces a further development of his work. He has carried the study of the rings in certain districts back to the date 700 B.C.; by examining the timbers in some ancient Indian buildings he was able to give the dates when the trees were cut, and thus to date the buildings. Dr. Antevs, of the University of Stockholm, has found correlation between the structure of clay layers in ancient lake-beds and the sunspot cycle. Both the tree-rings and the clay layers are supposed to depend directly on the rainfall, so it is really the latter that is correlated with the sunspots.

The work of both Dr. Douglass and Dr. Antevs has been honoured by the award of Research Corporation prizes, given through the Smithsonian Institution.

The Distance of Nova Pictoris.—The April issue of *Mon. Not. Roy. Ast. Soc.* contains a paper by Dr. Spencer Jones, giving the details of this investigation. Direct trigonometrical measures gave the negative parallax $-0{\cdot}009''$, with a probable error of $0{\cdot}007''$. This could only be taken as an indication that the distance is very great. An estimate was reached on the assumption that the increase of light was due to an expanding shell or series of shells of gas emitted by the star. The rate of expansion is assumed to have been uniform between the outburst and the maximum of light; it is also assumed that the effective temperature did not vary during this period. The rate of increase in the radius per day was calculated as 5·77 times the original value, while the spectroscope indicated a velocity of approach of 65 km./sec., which becomes 77 on allowing for the recession of the centre, which is 12 km./sec. Allowing for the fact that this is an integrated value over the whole disc, the parallax is deduced as $0{\cdot}0015''$, and this value is found to be practically independent of the initial temperature. At maximum the radius would be 384 times that of the sun. The absolute magnitude is deduced as 3·15 before the outburst and −7·9 at maximum.

A Possible Cometary Observation by Bessel in 1832.—Bessel observed an object that he described as a nebula on Nov. 8, 1832; its position for the equinox of 1825·0 was $2^h\ 42^m\ 5{\cdot}56^s$, N. Decl. 36° 46′ 46·7″. Many subsequent observers have found a faint star of mag. 9·3 in this place, but none of them could see any nebulosity round it; there is a note to this effect in "New General Catalogue". Prof. Schulhof suggested many years ago that there might have been a comet superposed on the star when Bessel observed it. The writer of this note has recently noticed that, if it was a comet, it may have been Tempel's comet of the November meteors. If so, the date of perihelion would have been Oct. 30, 1832, which is not very far from the date indicated by the recent calculations of the Computing Section of the British Astronomical Association. If this identity should be correct, the next perihelion passage will occur in November or December 1932. If the Bessel object was Tempel's comet, it would have been extremely near the earth at the time; the earth perturbations would probably be large enough to account for the small corrections needed by the elements to make them represent Bessel's observed position. There was quite a rich shower of Leonids in November 1832, though it was apparently surpassed by that of Nov. 12, 1833. Owing to the shift of the node, Nov. 17 is the probable date this year, and Nov. 16 in the two following years. The watch should be kept on neighbouring nights also, as it is difficult to predict the position of the meteors with great precision.

Research in Industry.

IN a lecture on "Research in Industry and Rationalisation", delivered before the Society of Swedish Engineers in Great Britain on May 27, Mr. Axel Y. Enström discussed the way in which research and rationalisation have become indispensable factors for the economic development of industry. Science and research have now come to be marshalled among the working tools of industry in daily use, and the post-War period can supply many examples of the fruitful association of scientific and industrial research. Mr. Enström considers that Sweden's ability to attain a position in the world's markets has largely depended on the purposeful incorporation of scientific research, well-equipped laboratories, and a highly qualified staff with her industrial activity. There are now in Sweden about fifty works' research laboratories, which employ some six hundred persons and represent all the large industrial undertakings. The total cost of the industrial research carried on in Sweden is probably about four to five million crowns.

Discussing the special characteristics of scientific and technical research, Mr. Enström suggested that spontaneous research, such as Röntgen's discovery of the Röntgen rays, is typical of the former, and the systematic research which Hertz based on Maxwell's equations is typical of the latter. Even in systematic research, however, fundamental or scientific research, as well as a high standard of scientific technique, may be essential. Disregard of fundamental scientific principles may lead to enormous waste in technical research, especially in experimental plant work. After such technical investigations on a metallurgical process in Sweden, involving an outlay of several millions, had been abandoned as fruitless, scientific investigations on the interaction of ore particles and gases yielded a solution. The importance in technical research of a thorough knowledge of the fundamental physical and chemical sciences cannot be overstressed, but such a combination is difficult to find.

Other factors in technical research which may eliminate much wastage of time and labour are mathematical analysis of the possibilities at an early stage in the investigations, and the thorough study of the information already existing either in the literature or in technical sources before experimental work is undertaken. Related to these factors is the standard of experimental technique of the investigator and his knowledge of the possibilities and limitations of that technique. Similar qualities are increasingly involved in technical analysis and process control, and the essential factor in all the scientific control and development of industry may thus be briefly described as clear thinking.

In this description it is easy to include rationalisation, which, like technical research, aims at improving, increasing, or cheapening production. While suggesting that discussion as to whether the continued displacement of labour by machinery is justifiable is premature, Mr. Enström considered that rationalisation must progress with natural necessity. We have no general view of the correct proportion between direct production for consumption and production of machinery or tools. Economic history suggests that equilibrium is continually re-established on a fresh basis when the proportion is disturbed. Standardisation is an important element in rationalisation, and the research work on manufacturing processes not only leads to standardisation of processes and improved efficiency but also may frequently have a far-reaching rationalising effect. The application of scientific principles and methods of investigation to industrial problems inevitably leads sooner or later to the application of the same principles and methods to the conduct of the whole industry. Technical research and scientific management are thus two important aspects of rationalisation, and the future of industry largely depends on our ability to produce industrial leaders competent to evaluate these factors, with the economic, social, and other factors involved.

The Flying Fox in Australia.

TWO years ago, Mr. F. N. Ratcliffe was appointed by the Commonwealth Council for Scientific and Industrial Research to obtain for it as complete a picture as possible of the flying fox (*Pteropus* spp.) population of Queensland and New South Wales, its significance and extent, the relations of the different species one to another, the nature and cause of their migrations, the individual and collective habits of the animals, and the extent and value of the economic losses involved. Fruit-growers had at times complained loudly of orchard depredation by this pest and demanded governmental action to exterminate it. The Council was somewhat sceptical about the alleged facts: hence this inquiry, which received financial support from the Commonwealth, New South Wales, and Queensland Governments. Mr. Ratcliffe has now completed his work, and furnished to the Council a report which is not only most interesting reading but also is admirably fearless in its criticism of current ideas and practices.

Four species of flying fox are found in Australia: *poliocephalus*, *Gouldi*, *conspicillatus*, and *scapulatus*. They are practically confined to coastal areas, and their numbers, which cannot be accurately assessed, must amount to many millions in the numerous 'camps' scattered along a north–south stretch of some two thousand miles. There has, no doubt, been a diminution in numbers as settlement has progressed in New South Wales and South Queensland, the present population amounting probably to only about half that of early days. As in the past, so to-day, the principal food of all species is undoubtedly blossom, chiefly of eucalypts, and Mr. Ratcliffe has been forced to the conclusion that the current opinion that the fox is guilty of appalling destruction in fruit plantations is a gross exaggeration, so far at least as the commercial fruit crop of Queensland is concerned. Attacks on orchards are more an indication of general food shortage than evidence that cultivated fruit is an essential part of the animal's food supply. Such fruits as bananas, pineapples, citrus, pawpaws, and apples are, as a matter of fact, too hard for the weak dentition of the little red fox (*P. scapulatus*), which is equal in numbers to all the other species put together. *P. poliocephalus*, however, finds no difficulty in attacking these, when ripe: though here again it is important to remember that normally all these fruits, except perhaps citrus, should be picked for market while still unripe and therefore unattractive to the foxes. In other words, if the growers harvest these particular crops in satisfactory fashion, the loss to the commercial fruit industry in Queensland resulting from flying fox infestation should be almost trifling.

One must not forget, however, that what may be called 'back garden' fruit is usually left on the trees until almost, or quite, ripe, and therefore is far more attractive to, and more readily attacked by, the bats than the greener product. This probably accounts for far more general popular outcry against the animals than the actual economics of the situation justify. Still, looking at the matter merely from a business point of view, if the fox is not a menace to the large-scale commercial industry, there would seem to be little valid reason for any considerable expenditure of public money on its control.

Nevertheless, big losses occasionally occur, notably where soft fruits (figs, peaches, nectarines, etc.) are grown. The problem presented by these is much greater in New South Wales than in Queensland. Hence Mr. Ratcliffe has felt it necessary to discuss critically various methods which have been proposed for coping with the trouble. Control through direct destruction by shooting, he rules out as a physical and economic impossibility. Attack by contagious or infectious disease is probably hopeless. There is now such a mass of experience indicating the improbability that control can ever be brought about in this way that it seems not worth while even to initiate experiments. The use of poison gases in the camps is almost impracticable and, on good evidence, ineffective. Flame guns are useful to an extent, but objectionable in many respects, including that of the cruelty involved. As for the 'scalp bounty' system, as adopted by Queensland, Mr. Ratcliffe's condemnation of it is as emphatic as it is just. He shows that in one important area, if every penny of the money provided by the Pests Destruction Board as bounty were spent solely on foxes, at 3*d*. per animal, the total destruction would probably be less than 1 in 200 of the normal population. Even then, *P. scapulatus*, because the least intelligent species, would usually be the most heavily hit: as it is also the least troublesome, money spent on it would be sheer waste.

Apart, however, from attempts at mass control, much protection might be afforded in small localised areas by systematic use of deterrents and poisons by the fruit-growers, and recommendations are made for the encouragement of such practices.

It seems, then, that the economic significance of the bat trouble in Australia is not really very great; it has certainly been exaggerated. The fox is a nuisance rather than a pest, affecting chiefly the small home grower and not the commercial fruit industry. Possibly, as Mr. Ratcliffe suggests, the reason for the prevalent exaggeration is partly psychological. The bat is nocturnal, noisy and smelly, and usually infested with parasites; in fact, decidedly detestable. It is no wonder, perhaps, that Mr. Ratcliffe found astonishing numbers of individuals prefacing their information regarding the foxes with a statement that they were "stinking, lousy brutes". Such an attitude is not without significance when one is seeking an unbiased assessment of the economic importance of a nuisance.

Be that as it may, the upshot of this very interesting inquiry should be to convince Australia that one, at least, of her pests is not so bad as it has been represented, and is not likely to become any worse. This will be some comfort to the Council for Scientific and Industrial Research, which finds decreasing funds and increasing responsibilities to be matters of grave embarrassment at the present time. A. C. D. R.

Young's Theory of Colour Vision.*

Although Thomas Young is well known as the founder of a theory of colour vision, his contributions to the theory are limited to two or three short paragraphs, and there is no evidence that he himself attached much importance to them. He was the first who, starting from the well-known fact that there are three primary colours, sought for the explanation of this fact, not in the nature of light, but in the constitution of man. He wrote: "Now, as it is almost impossible to conceive each sensitive point of the retina to contain an infinite number of particles each capable of vibrating in perfect unison with every possible undulation, it becomes necessary to suppose the number limited, for instance, to the three primary colours—red, yellow, and blue . . . and each sensitive filament of the nerve may consist of three portions, one for each principal colour." He afterwards took red, green, and violet as the three primary colours. His other statement regarding colour is in connexion with Dalton's colour-blindness, of which he says: "It is much more simple to suppose the absence or paralysis of those fibres of the retina which are calculated to perceive red".

Although the three component theory as developed by Clerk Maxwell, Helmholtz, and others accounted well for many of the facts of colour mixture, it had also to account for other phenomena of vision, such as visual acuity, the luminosity curve, hue discrimination, simultaneous and successive contrasts, and colour-blindness. Recent work by Hecht and others has succeeded in solving many of these problems.

The determination of the luminosity curve, which physicists still persist in calling the 'visibility' curve, has been the subject of such accurate investigation that it can now be regarded as one of the soundest scientific data in the whole realm of vision.

Dalton may be regarded as initiating the scientific study of colour vision, and later work by Seeback and Clerk Maxwell strongly supports the view expressed by Young that cases of colour-blindness are reduced forms of normal vision. On this theory, the neutral points of the spectrum as seen by protanopes and deuteranopes are excellently explained by the points of decussation of their two remaining curves.

The fact that yellow is psychologically as distinctive a colour as red, green, or violet, and physiologically shows no evidence of composite character, was long regarded as a strong argument against the trichromatic theory, until Hecht proved conclusively that the sensation of yellow could be experienced by fusing binocularly the sensations produced by appropriate red stimulation to one eye and green stimulation to the other.

Research since Young's day has done nothing to bridge the gap between the physiological and the psychological response, but considerable progress has been effected by Holmgren, Kohlrausch, Lucas, and Adrian in elucidating the physiological response itself. The results of these workers on the photochemical reaction of the visual purple, and the accompanying changes in electrical potential of the retinal structures, all tend to show that the fundamental phenomena of vision all manifest themselves in the retina.

Finally, the researches of Pieron, especially those on colour responses to black and white stimuli, and those of Allen on induction effects as shown on the persistency curves resulting from previous stimulation of the retina by monochromatic light, all have a distinct confirmation bearing on Young's theory.

---

* Substance of a paper read by Sir John H. Parsons, F.R.S., before the Optical Society on June 11.

Taste and Chemical Constitution.

THE relationship between physiological action and chemical constitution has been investigated for a number of compounds by animal experiment, when it is easy to compare and contrast the effects on a variety of systems of closely related substances. In spite of much work on the subject, no wide generalisations are yet possible, although it has been frequently shown that a very slight alteration in the molecule may enhance or decrease a particular physiological action: as an example may be mentioned the varying pressor effects of adrenaline and compounds closely related to it. The question is still less susceptible to investigation when the relationship between chemical structure and taste or smell is considered, since the experimental subject must be man and the investigator has to rely upon his subject's subjective sensations and cannot measure objectively the effect of his stimulus.

There is no generally accepted classification of odours, but tastes are usually divided into four groups —sweet, sour, salt, and bitter. No comprehensive generalisation has yet been discovered, however, for the relationship between taste and chemical constitution. It has usually been supposed that different people will taste the same compound, although perhaps with different degrees of intensity. A. L. Fox, of Wilmington, Delaware, U.S.A., has, however, recently found that whereas some people find that phenyl thiourea has an extremely bitter taste, others will state that it has no taste at all. As a result of numerous trials, he has found that about 60 per cent can taste it, whilst to the other 40 per cent it has no taste. The intensity of the bitter taste in the former group varied considerably. The division into the two groups was not a question of sex, age, race, colour, or family: of a pair of identical twins, one tasted it, the other did not.

A variety of thioureas was then examined: all had a bitter taste to some people, no taste to others: the list included *p*-ethoxy phenyl thiourea, and a number of other phenyl thioureas, naphthalene thioureas, diphenyl thiourea, and 2, 2′ dimethoxy, 5, 5′ dimethyl diphenyl thiourea. With diorthotolyl thiourea, however, the group of non-tasters was large, since some of those who had tasted all the previous compounds failed to taste this. With di-para-tolyl thiourea the taste was first sweet, then bitter. Dicrotyl thiourea and dibenzyl thiourea were also bitter to the tasters, but thiourea itself had an unpleasant taste to both groups, and tetramethyl thiourea appeared sour to both. The bitterness, therefore, appeared to be associated usually with compounds containing a benzene or naphthalene ring and thiourea: removal of the sulphur atom and replacement with oxygen can completely alter the taste, since *p*-ethoxy phenyl urea has a very sweet taste.

The failure of certain people to taste the bitterness of these thioureas is analogous to the failure of people to smell certain verbenas, as observed by Blakeslee. Some people found certain verbenas very fragrant, whilst to others they appeared to have no smell. With other verbenas, however, the two groups were reversed. It is, in fact, a well-known phenomenon that the sense of smell is very capricious, certain people being much more sensitive to some odours than others. It is obvious that this inability to smell or taste must be borne in mind when experiments are carried out on the relationship between the sensation and chemical constitution: errors may be avoided by the use of a sufficient number of subjects.

University and Educational Intelligence.

ABERDEEN.—At the graduation ceremony held on July 8 the honorary degree of LL.D. was conferred, among others, upon Prof. John Garstang, John Rankin professor of the methods and practice of archæology in the University of Liverpool. The ordinary degree of D.Sc. was conferred upon W. A. Carr Fraser, for a thesis entitled "Critical Studies in Hæmocytometry".

LONDON.—The external degree of D.Sc. in chemistry has been conferred on Aruppillai Kandiah (private study), for a thesis entitled "Studies in Dicyclic Systems. Part I. The Chemistry of 2-Substituted cis- and trans-Hexahydrohydrindenes. Part II. The Influence of cis- and trans-Hexahydrohydrindene Nuclei on the Carbon Tetrahedral Angle".

DR. T. J. DRAKELEY, head of the Chemistry Department and School of Rubber Technology at the Northern Polytechnic since 1919, has been appointed principal of the Polytechnic in succession to Dr. R. S. Clay, as from Jan. 1, 1932.

A VACATION course for teachers will be held at Bingley Training College on July 29–Aug. 12. The opening lecture, entitled "The Educational Revolution and its Steps of Progress", will be given by Prof. Patrick Geddes, on the first evening. Other evening lectures include Prof. T. H. Pear on "Learning how to Study" and Dr. G. H. Green on "Racial Bias and International Understanding". In the work of the senior school, the question of biology will be dealt with by Prof. R. D. Laurie throughout the course, and Sir Percy Nunn will deal with mathematics. A summer vacation course for physical training will be held at the Grammar School, Ilkley, on Aug. 3–15. Application for entrance to either course should be made to the Education Officer, County Hall, Wakefield, Yorks.

THE directors of Messrs. H. K. Lewis and Co., Ltd., booksellers and publishers, held a reception on July 9 to inaugurate their new building at the corner of Gower Street and Gower Place, adjoining University College, London. Designed by Mr. J. R. Moore Simpson, the new building is of steel-framed construction, faced with stone to harmonise with the adjoining College buildings, and part of the accommodation on the upper floors is reserved for the use of the College. Sir Gregory Foster, who presided over a large company, including many of the staff of University College, wished success to the firm in their enlarged undertaking. He was supported by Prof. Thane, who discussed 'text-books', stressing their increasing size in recent years, an increase not fully justified. Messrs. Lewis, established in 1844, now include, in addition to their main activity of bookselling, a publishing department, circulating library, and second-hand book department. As publishers they have specialised in medical books, and their catalogue includes many honoured names in the medical world, such as Jenner, Burdon Sanderson, Lister, and Osler. In addition to books, scientific journals are published, including the *British Journal of Dermatology*, *British Journal of Experimental Pathology*, and the *Clinical Journal*. A large stock of anatomical models, diagrams, and charts is available. The record of the firm is one of continuous growth, with every indication of acceleration owing to the new accommodation. A pleasing feature of the reception was the general recognition of the work of booksellers, publishers, and librarians as contributors to scientific and educational progress.

Birthdays and Research Centres.

July 12, 1863.—Dr. L. Ch. Albert Calmette, For.Mem.R.S., sub-director of the Pasteur Institute, Paris.

I am conducting researches on snake venoms, antivenomous serums (1892–1900); bubonic plague and serotherapy; tuberculosis, mechanism of infection, and preventive vaccination of babies with B.C.G.

July 22, 1865.—Sir Richard A. S. Redmayne, K.C.B., consulting mining engineer, professor of mining in the University of Birmingham, 1902–8, and H.M. Chief Inspector of Mines, 1908–20.

My object of chief investigation now in progress is the freeing of coal from the seam by non-inflammable means. The importance of this is obvious when one considers the great loss of life in gassy and/or dry and dusty coal-mines from explosions initiated by the flame of explosives.

A commercially possible process for the liquefaction of coal is a subject worthy of investigation. Were it possible to liquefy coal profitably the whole outlook of the coal-mining industry of the world, and Great Britain in particular, would be transformed for the better.

The commercial production of beryllium is also a subject to which attention might usefully be given. The importance of beryllium as a valuable alloy with copper, aluminium, and other metals has emerged recently.

The devising of an economical method of extracting alumina from bauxite containing 8 per cent and more of silica; as well as the extraction of alumina from lower grade ore generally, including clays, deserve attention. The high-grade ores of aluminium (bauxite) are not very extensive, and it is in the highest degree desirable with the greatly increasing importance and output of aluminium that a practicable and profitable means of extraction of alumina from the lower grade ores and, if possible, from clays generally should be found.

July 24, 1856.—Prof. Émile Picard, For.Mem.R.S., member of the French Academy, and permanent secretary of the Paris Academy of Sciences.

J'ai de l'intérêt pour l'analyse mathématique. la théorie des fonctions et la théorie des nombres. J'ai publié divers ouvrages sur l'histoire et la philosophie des sciences.

Societies and Academies.

London

Geological Society, June 17.—**Olaf Holtedahl**: Some general structural features of the arctic and adjacent regions. The huge region comprising the Canadian and the Baltic Shields and the areas lying between them represents a sort of structural unit which may be more or less symmetrically divided by two lines, one north and south, the other at right angles to it, crossing each other in the central part of Greenland. Although Baffin Land and the western zone of Fennoscandia had a somewhat different history in ancient geological times, yet each may be regarded as the reflected image of the other, both consisting of mountain ranges with the highest elevation on the side bordering the adjacent deep sea area. In the northward continuation of these two zones, in Ellesmereland and Spitsbergen respectively, and at the north end of Greenland, are other zones where the distribution of the various formations tells of a somewhat similar inclination of the earth's crust; an inclination away from central Greenland, the previously mentioned structural centre. Thus there is, in a roughly ring-shaped belt, an inclined elevation of recent, probably younger Tertiary, date, and it seems a natural conclusion that this particular elevation has been of fundamental importance in the gathering of snow, which in Quaternary time developed into the modern ice-fields, the centre of which coincides with the above-mentioned structural centre.—**James Archibald Douglas** and **William Joscelyn Arkell**: The stratigraphical distribution of the cornbrash: (2) The north-eastern area. Attention has been chiefly confined to the brachiopod zones, and their distribution throughout the area is indicated by a detailed account of many typical exposures. Further readjustment of Buckman's zonal table has been found necessary in respect of the zones of *Tegulithyris bentleyi* and *Obovothyris stiltonensis*. The evidence for and against penecontemporaneous erosion is discussed.

Paris.

Acedemy of Sciences, May 26.—**Charles Nicolle** and **Ugo Lumbroso**: The immunity following a natural attack and cure of trachoma against an experimental re-inoculation of the virus.—**A. F. Holleman** was elected *Correspondant* for the section of chemistry.—**Long**: The *W* surfaces.—**Maurice Potron**: A fundamental theorem of the theory of finite continued groups of transformations.—**Marcel Winants**: Determination of a function of functions by means of an integral equation.—**Teissié-Solier**: The conditions of use of a Pitot tube and the impulse of a turbulent jet on a plate.—**J. Le Roux**: The impossibility of a law of gravitation for an aggregate comprising only two material points.—**Ch. Sadron**: The ferromagnetic saturation of elements other than iron, nickel, and cobalt, and the periodic system.—**L. Bull** and **Mlle. Suzanne Veil**: The optical study of the secondary Liesegang rings.—**L. Bert** and **R. Annequin**: A new method of synthesis of einnamic aldehyde and its homologues substituted in the nucleus. $C_6H_5 . . CH_2 . CH : CHCl$, ω-chlorallylbenzene is converted into $C_6H_5 . CH_2 . CHCl . CHCl_2$ (or the corresponding bromine compound), and this, by heating with sodium ethylate in excess, into the diethyl acetal of cinnamic aldehyde. The reaction is general, and can be applied to the preparation of homologues of cinnamic alhehyde.—**J. D. Strelnikov**: The influence of the solar radiations on the temperature of the bodies of insects. The body temperature of insects is raised by exposure to the sun, and the organism of an insect is very sensitive to slight changes in the surrounding medium.—**Michel Polonovski** and **Albert Lespagnol**: Two new sugars from human milk, gyrolactose and allolactose. In the course of analyses of human milk by the ordinary polarimetric and reduction methods the divergences found suggested the presence of sugars other than lactose. Two new sugars have been isolated as the result of a long series of fractional crystallisations, and these have been named gyrolactose and allolactose. The properties of these two sugars are found to explain the abnormalities found on analysis.

Cape Town.

Royal Society of South Africa, April 15.—**B. Farrington**: Vesalius on vivisection. This paper is a translation of the last chapter of the *De Humani Corporis Fabrica* of Vesalius, which bears the title "Some Observations on the Dissection of Living Things". Though Vesalius did not advance the study of physiology to anything like the same degree as he did the science of anatomy, his book is, none the less, in the words of Sir M. Foster, "the beginning not only of modern anatomy but of modern physiology". The physiological experiments described by Vesalius have a direct connexion with the series of observations on living animals that enabled Harvey to demonstrate the circulation of the blood.—**J. H. Power**: On the herpetological fauna of the Lobatsi-Linokana area. An unexpected result of the author's collecting at Linokana was the discovery, in many cases, of different species, of certain genera, from those found at Lobatsi. The two localities are connected by a narrow valley between two ranges of hills, seemingly an admirable condition for ensuring that the reptile and amphibian faunas should be the same. The list of species collected materially extends the range of many species. The relationships of *Gerrhosaurus flavigularis* and *G. nigrolineatus*, and *Bufo tuberculosus* and *B. regularis gutturalis*, are discussed.—**J. W. C. Gunn** and **D. Epstein**: The reaction of *Xenopus* to digitalis. It has been stated that in *Rana* there are unexplainable variations in the response to digitalis as shown by the differences in the minimal lethal doses in individual animals on any one day, in groups of animals from day to day and in other ways. Such variations are not seen with *Xenopus* even when kept in captivity for several months. It is therefore superior to *Rana* for the biological assay of digitalis by any of the frog methods.—**D. Epstein, J. W. C. Gunn, E. Epstein**, and **G. Rimer**: The adrenal secretion of *Xenopus lævis*. Morphologists claim that no adrenal bodies are present in *Xenopus*, and various hypotheses have been brought forward to account for the absence of these glands. The authors have shown experimentally the presence of adrenaline in extracts of the kidneys of *Xenopus*. The kidney tissue itself contains no adrenaline, but the active substance is derived apparently from thin yellow streaks present on the ventral surfaces of the kidneys. These streaks probably represent the adrenal glands of *Xenopus*. This has been confirmed histologically by the demonstration of chromaffin tissue.

Cracow

Polish Academy of Science and Letters, Feb. 9.—**J. Fridrichson**: The fluorescence of manganese vapour.—**Mlle. M. Ney**: The enlargement of diffused lines without change of frequency in the Raman effect. A study of the lines diffused in quartz and in benzene shows that a marked widening of the lines occurs in benzene, but in quartz at 180° C. and at 500° C. no such widening can be observed.—**T. Tucholski**: The spectra of metals obtained by explosive reactions. Studies of the spectra obtained by the explosion of metallic picrates. Explosion spectra are essentially flame spectra, but with some additional characteristic features. The explosion temperatures are between 1900° C. and 3200° C.—**T. Banachiewicz**: An application of the periodograms of Sir Arthur Schuster.—**W. Swietolawski, Mme. M. Rybicka**, and **Mme. W. Solodkowska**: An adiabatic microcalorimeter adapted to the measurement of the specific heat of solid and liquid substances. A study of the conditions of working with the microcalorimeter, with special reference to the correction for the gas contained in the apparatus and to the error introduced by evaporation or adsorption of water.—**W. Swietoslawski** and **Mlle. E. Bartoszewiczowna**: (1) The application of the adiabatic microcalorimeter to the determination of the heat of adsorption and of vaporisation. The quantity of liquid required in these determinations is 0·01–0·1 gm., and the errors are 0·2–0·7 per cent for heat of vaporisation and 0·6–1·7 per cent for heat of adsorption.—(2) The determination of the heat of vaporisation in the fatty alcohol series with the adiabatic microcalorimeter.—**W. Jacek**: The velocity of the solution of marble in acids.—**M. Karasinski**: The determination of fluorine as CaF_2 according to the method of Berzelius. Instead of adding sodium carbonate to secure an easily filtrable precipitate, the author attains the same result by evaporation to dryness and gentle ignition, followed by extraction with water.—**K. Dziewonski** and **J. Moszew**: The synthesis of α-ethylacenaphthyl ketone.—**St. Kreutz**: Heulandite occurring in the Tatra granites and the volcanic rocks in the neighbourhood of Cracow.—**St. Kreutz**: Crystals of topaz from Jahodenka in the neighbourhood of Horoszki (Wolhynie).—**S. Kozik**: The optical properties of mixed crystals of ammonium and sodium tartrate and of rubidium and sodium tartrate.—**J. Broder**: The diabases of Niedzwiedzia Góra and the formations which accompany them. Chemico-petrographic study.—**J. Zerndt**: Megaspores, characteristic fossils of the productive carboniferous strata.—**W. Szafer**: The ancient diluvial flora of Hamernia on the Lubaczówka.—**Mlle. M. Ziemba**: Biological researches concerning the flowers of the eastern Carpathians.—**M. Gieysztor**: Contribution to the knowledge of the Rhabdocœles of Spain.—**St. Markowski**: Researches concerning the helminthological fauna of the Corvidæ of Poland.—**A. Kulczycki**: The physiological degeneration of the striated muscles.—**Mlle. S. Vrtel**: Histological researches concerning the thyroid gland. The thyroid gland of selacians.—**J. Tur**: New studies on diplogeneses with abortive centres.—**St. Wajda**: Cytological researches on the secretion of the thread-producing glands of the larvæ of Trichoptera.—**J. Wilburg**: The development of the blood-vessels in the foot and toes of *Sus scrofa domestica*.—**M. Rose**: The cellular structure of the cortical substance of the brain of the rabbit.—**W. Heinrich** and **T. Strzembosz**: The function of the capillary vessels with respect to concentration of attention.

Geneva.

Society of Physics and Natural History, Mar. 5.—**Fern. Chodat** and **Suzanne Kann**: Study of the diurnal course of transpiration of two alpine plants. These experiments were made at the Bourg St. Pierre alpine garden at an altitude of 1650 metres. For *Eryngium*, the authors have detected two clear maxima at 10.30 A.M. and 3.30 P.M. respectively. *Adenostyles alliariæ*, a plant requiring shade, has, on the contrary, constant transpiration from morning to evening.—**Fern. Chodat**: The action of light upon cellular permeability. The author interprets the experiments described above as being due to the higher proportion of rays of short wave-length at high altitudes. This explains the difference which exists between the transpiration of plants at low and high altitudes.—**Louis Deshusses** and **Jean Deshusses**: The distribution of the pyrethrins in the pyrethrum flower. The stems contain from a tenth to a fourteenth of the total pyrethrins found in the flower of the same growth. Hence, in the preparation of pyrethrum insecticides in the form of extracts or powders, it is necessary to take this fact into account: this is very important from the point of view of the toxic power of the product obtained.

Leningrad.

Academy of Sciences (*Comptes rendus*, No. 19, 1930).—**B. Segal**: A generalisation of Brun's theorem.—**I. Balanovskii**: The computation of rectangular coordinates of basic stars on astrophotographic charts.—**E. Semičev**: The fundamental features of electrodynamic relations in electromagnetic machinery. In no electrodynamic process is the electromagnetic energy completely transformed into mechanical work. In other words, every electrodynamic process in which the system accomplishes positive, or negative, mechanical work is characterised by some reactive energy taking part in it.—**I. Kablukov** and **F. Perelmann**: The heat of combustion of certain organic halogenic compounds. Determinations of the heat of combustion of dichlorethylene, chloroform, chlorbenzene, dibromethylene, bromoform, and brombenzene.—**N. Williams**: Hydrogenation of some derivatives of furfurane.

Comptes rendus, No. 20, 1930. — **F. Loewinson-Lessing, V. Mitkevitch**, and **A. Turcev**: Experiments in the artificial magnetisation of limonites. Limonites submitted to magnetisation in the electromagnetic field of 2500 gauss, after having been heated to 400°-500° C., do not exhibit any proportionality of the intensity of the magnetisation and the content of the ferrous oxide. The magnetisation depends on the degree of trituration and is more intense in the case of powdered substances. There is a direct relation between the intensity of magnetisation and the manganese content.—**B. Brunovski** and **K. Kunasheva**: The radium content of certain plants.—**V. Vernadskii**: The concentration of radium by plants. Determinations of the radium content of *Lemna* and of the water in which it lives proved that the plant concentrates up to 200 and even 477 times as much radium as is in the water, there being a great difference between plants from different localities. In some cases, it is impossible to detect radium in the water, but its concentration in the plant is very high.—**N. Prokopenko**: The deposits of solid kaolin in the Dzhungarian Alatau.—**E. Litchko**: Observations on the regeneration of the extremities in the axolotl under the influence of X-rays. Local radiation for 60 minutes does not affect the regenerative abilities. When the whole animal was subjected to the radiation for 16 minutes but one foot was screened, that foot was able to regenerate, though the animal could not survive more than two months.

Comptes rendus, No. 21.—**S. P. Kostychev, V. Gvaladze**, and **P. S. Eliasberg**: The formation of pyruvic acid in lactic fermentation. A method is described for the isolation of the pyruvic acid in the presence of sugar.—**V. Gulevitch**: Methyl-guanido-oxalic acid (creaton) as a constituent part of muscles. The formula of the creaton was found to be $HN : C (NH_2) . N(CH_3) . CO . COOH$. It is possible that creaton, like glutathione, takes part in the oxidation processes of the organism.—**L. Kantorovitch**: Certain developments of the polynoms of S. N. Bernstein.—**B. Numerov**: The interpretation of gravimetric observations in the case of a single surface of contact.—**B. Numerov**: The construction of isograms after observations with a gravitational variometer.—**B. Barovskii**: Description of a new species of the genus *Macrolycus* Waterh. (Coleoptera, Lycidæ). *Macrolycus æmulus*, sp. n., is described from the Ussuri region and Manchuria.

Comptes rendus, No. 22.—**A. A. Borisiak**: Charles Depéret (obituary).—**N. Nasonov**: On *Acrorhynchus baicalensis* Rubtzoff (Turbellaria, Rhabdocœla) from Lake Baikal. This species does not belong to the genus *Acrorhynchus* and is more closely allied to *Kainocystis*, so that it cannot be considered a representative of marine Rhabdocœla.—**M. A. Menzbier**: The combination of factors to which the origin and the development of terrestrial vertebrates is due. Free movement of the head is connected with the replacing of the branchial apparatus by lungs, this leading to the final victory of aerial over aquatic respiration.—**L. Kantorovitch**: Certain developments of the polynoms of S. N. Bernstein (2).—**N. Terebinskii**: Experimental studies of the faults of cardiac valves.—**N. O. Olenev**: Scientific results of the expeditions in 1928 and 1929 to Kazakstan for the study of parasites of domestic animals. A list of parasites, with their hosts, is given.

Comptes rendus, No. 23.—**A. Tugarinov**: A fossil ostrich from Transbaicalia. Fragments of ostrich eggs have been found in several localities. The structure of the shells shows some relation to the recent North African ostrich, but there are considerable differences.—**V. Barovskii**: Description of a new species of the genus *Pyropterus* Muls. (Coleoptera, Lycidæ) from Transcaucasia. *Pyropterus shelkonnikovi*, sp. n.—**A. A. Birula**: A preliminary communication on the rodents from the quaternary deposits in the Crimea. The quaternary fauna included 18 species of rodents, while at present there are only 14 in the Crimea.—**B. A. Kusnečov**: A new species of jumping mouse (*Alactagulus shitkovi*, sp. n.) from Semiretchie.—**P. Schmidt**: Two rare Japanese sharks, *Proscyllium habereri* Hilgendorf and *Apristurus macrorhynchus* Tanaka. Synonyms and supplementary description of the two species mentioned.

MELBOURNE.

Royal Society of Victoria, April 9.—**O. A. Mendelsohn**: Some observations on the bacterial count of sea-water as determined by samples taken at intervals on a voyage between Australia and Europe.—**R. B. Withers**: On the development of the tabulate coral, *Pleurodictyum megastomum*. The author works out the mode of growth of the *Pleurodictyum megastomum*, Dun, Yeringian (Upper Silurian) of Victoria, Australia. To the eighth corallite, growth proceeds on a definite plan by budding from the initial corallite. This neanic stage is followed by the ephebic stage, when the corallum enlarges without further addition of corallites. The gerontic stage is characterised by the irregular growth of a second ring of corallites, and the insertion of others by intermural gemmation. *Pleurodictyum lenticulare*, Hall sp., Lower Helderbergian (Lower Devonian) of North America, develops in a similar manner.

PRAGUE.

Czech (Bohemian) Academy of Arts and Sciences (Second Class, Natural Sciences and Medicine), Dec. 12.—**M. Pelíšek**: The rolling of a helix on a congruent helix.—**R. Lukes**: The action of Grignard's reagent on *N*-methyl pyrrolidon; new synthesis of substituted pyrrolines. Chief products were *1*-methyl-2-alkyl-pyrrolins next to *1*-methyl-2 . 2-dialkyl-pyrrolidins. The former were isolated as perchlorates, the latter as picrates.—**V. Prelog**: The sapogenin of beetroot. Chromic acid oxidises sapogenin to a ketonic acid and di-hydroxy-lactone. With sulphuric acid it yields carbon monoxide, hence its carboxyl is bound to a quaternary carbon atom; the action with tetranitro-methane indicates inactive double linkages.—**L. Šimek**: Graphical solution of reactions and axial forces in a special plane system of rods.—**L. Seifert**: A system of surfaces of third order which touch a given surface of third order in points of plane intersection.—**B. Brauner**: A philological note concerning some terms of modern scientific nomenclature.

Jan. 16.—**F. Záviska**: Notes on the study of universal ether. Critical remarks on the theory propounded by V. Posejpal.—**K. Domin**: Geobotanical excursion to the mountain Vysoká in the Little Carpathians.—**F. Němejc**: Seeds of *Alethopteris rubescens*.—**A. Glazunov**: The nature of a crystallisation centre. From one crystallisation centre grows a series of crystals forming one, usually heterogeneous, grain (crystallite).

Mar. 6.—**J. Petrbok**: Molluscs of the Pleistocene terrace of the Danube near Russe in Bulgaria.—**K. Petr**: The separation of roots of algebraic equations according to the real parts.—**B. Dratvová**: The problem of causality.—**Hrubý**: Biometric observations on blossoms of *Anemona nemorosa* L.—**L. Borovansky and Pexiderová**: The growth of the body and the progression of ossification in girls from birth to eighteen years of age.

Electro-Chemical Apparatus embodying Electro Analysis of Metals, Electrometric Determination of Hydrogen Ions, and Conductivity of Electrolytes. (List No. 80c.) Pp. 44. Catalogue of Surplus Stock Apparatus including Balances and Weights, Glassware (Graduated and Ordinary), Hardware, Metal and Porcelain Ware. (List No. SS 101H.) Pp. 20. (London: A. Gallenkamp and Co., Ltd.)

Diary of Societies.

FRIDAY, July 17.

Institution of Municipal and County Engineers (South Midland District Meeting) (at Winchester Street, Acton), at 2.15.—W. G. Cross: Some Recent Works in Acton.—S. W. Slight: New Sewage Pumping Station.—H. Atkinson: New Works Depot.

TUESDAY, July 21.

Royal Society of Medicine, at 5.30.—General Meeting.

London Natural History Society (at London School of Hygiene and Tropical Medicine), at 6.30.—Informal Meeting.

CONGRESSES.

July 17 to 25.

British Medical Association (at Eastbourne).

July 24 to 30.

British Commonwealth Education Conference (at Bedford College).—Subject: Education in a Changing Empire:—

Education in India.
Individual Education.
Modern Psychology in Education.
Examinations and Tests.

July 26 to 31.

International Congress on Radiology (at Paris).

SUMMER MEETING.

July 18 to 23.

Institution of Electrical Engineers (in Northern Italy and Western Switzerland).

SATURDAY, JULY 25, 1931.

No. 3221, Vol. 128]

Sterilisation and Mental Deficiency.

THE conditions which exist in a modern organised community are so exceedingly complicated that ability above the ordinary is demanded of those who would cope with them. The environment which man has created is not the optimal for many biological types, and this is certainly true of the certifiable mental defectives, whose numbers have doubled during the last twenty years, and of whom it is estimated there are now no less than 300,000 in England and Wales alone (Report of the Mental Deficiency Committee of the Boards of Education and Control, 1929). It has long been recognised that these require a special environment of their own in which they are not forced to compete with their normal fellow-men, and where they are out of harm's way; and so, for them, appropriate institutional accommodation has been devised. But the country is not prepared to find the money wherewith to provide such segregation for 300,000. In fact, only about 25,000 are thus sheltered. A further 50,000 are under guardianship, whilst the rest are scattered amongst the general population, relatively uncontrolled and unprotected, to constitute a most serious social problem.

The survey of the Royal Commission on the Care and Control of the Feebleminded (1908) was necessarily imperfect and incomplete, but this cannot explain away the startling fact that in twenty years the incidence of this incurable condition has increased from 4·6 to 8·56 per thousand. It is certain that there has been an actual increase of appalling magnitude. Since there is evidence to show that in a great many instances mental deficiency is genetic in origin, it is reasonable to assume that the increase is due, partly or largely, to the production of mentally defective offspring by mentally defective parents and by others who, though they themselves are not mentally defective, nevertheless transmit the corresponding hereditary factors. If this is so, then it must be expected that the incidence of mental defect in the population will continue to increase, unless the production of mentally defective children is checked; and the only sure method of reducing it is that of denying parentage to all who are likely to produce offspring exhibiting the condition.

Until we know exactly the genetic basis of hereditary mental defect, we cannot possibly deny parentage to the normal who carry the genetic factors corresponding to it in their hereditary constitutions. We can only teach and plead that any normal couple who have produced a men defective child should have no more children. But if the condition is genetic in many or all cases, no matter what the exact genetic basis of it may be, we cannot be mistaken in attempting to deny parentage to the certifiable mental defectives. To the eugenist, who holds the view that the condition is most commonly the expression of a biologically and socially undesirable hereditary constitution, the Report of the Mental Deficiency Committee of the Boards of Education and Control is as writing on the wall, foreshadowing the decay and doom of our human stock: for, since there must be harmony between the size of a population and the resources of its country, if the mental defectives increase, normals must decrease proportionately. No wonder there is a widespread interest in this matter, and that statesman, economist, sociologist, and biologist are in favour of legalising the voluntary sterilisation of mental defectives as provided for in a Bill brought before the House of Commons by Major A. G. Church on July 21; though unfortunately leave was not given for the Bill to be printed, so that it will not have a second reading.

Mental deficiency cannot be cured. The only possible treatment is the segregation of the mental defectives in appropriate institutions. If some or much mental deficiency is genetic in origin, as much care must be given to the children of the next generation as to the mentally defective individuals of this. So long as institutional treatment implies non-propagation, all is well; but if such segregation is insufficient or incomplete, then that portion of society which cares for the future as well as for the present must claim the right to prevent propagation on the part of the certifiable mentally defective. So long as medicine cannot cure the condition, society must claim the right to prevent the repetition of an hereditary blunder which yields individuals who cannot, in virtue of their organic inheritance, adapt themselves to prevailing social conditions, and who, because of their helplessness and lack of restraint and responsibility, hinder the further evolution of man and of society. The majority of rationally-minded people are agreed that every individual, including mental defectives, shall enjoy as much personal liberty as is consonant with the well-being of society, but insist that society can claim the right to protect itself, by all means at its disposal, from all those forces which threaten its existence.

The object of this Bill is to make the sterilisation of mental defectives, by such operative interference as vasectomy or salpingectomy, a lawful act, upon their own application or that of their parents or guardians. Its purpose is the sterilisation of mental defectives prior to their discharge from institutions; it also makes it possible for a defective to be sterilised voluntarily, with the sanction of the Board of Control, without being sent to an institution. The voluntary nature of the Bill is illustrated by the following safeguards: before an operation for sterilisation may be performed, the patient's consent must be given, if he or she be capable of expressing willingness or otherwise; secondly, the spouse or parents or guardians have to agree; the consent of the Board of Control must be obtained; and, finally, the operation must be approved by some judicial authority, such as a bench of magistrates. Only when these conditions have been observed can the judicial authority authorise the performance of the operation.

Undoubtedly, it is very necessary in this community to assume that any Bill dealing with such a matter as this will meet with considerable opposition, for personal opinions based on emotional bias are commonly more welcome than rational argument in accord with established fact. We may thus assume that the promoters of the Bill are presenting their minimum demands, fashioned in such a way as not to offend those whose opinions on this matter are really of no account but whose votes are important. The Bill is a soft-metalled pocket-knife which is to be used to hack away the steel ropes of mental deficiency which now entangle society. It cannot reduce the incidence of mental deficiency in Great Britain with any reasonable speed. Relatively few of the 300,000 mental defectives will be sterilised until spouses, parents, guardians, judicial authorities, as well as mental defectives themselves, have been persuaded that sterilisation by vasectomy and salpingectomy is to be desired, not only from the point of view of the patient, but also, and especially, from the point of view of society.

It is to be noted that the promoters of the Bill do not suggest that sterilisation should replace institutional segregation. They rightly hold the view that since institutional treatment is not available for all, and is commonly incomplete, sterilisation should be an auxiliary method of preventing propagation by mental defectives. Too much stress must not be laid on the suggestion that sterilisation will greatly diminish, if not entirely eliminate, mental defect. Until we know that mental defectives of one generation are responsible for more mental defectives in the next than are normal individuals carrying the genetic ingredients of this condition, it is impossible to form an accurate estimate of the reduction in the incidence of mental deficiency which would follow upon sterilisation of all mental defectives in a single generation. Nevertheless, whatever be the size of the contribution of mental defectives of one generation to mental deficiency in the next, so long as there is a contribution, then we are justified in advocating sterilisation of the certifiable mental defective if non-propagation can thus best be ensured.

It is not claimed in this Bill that the wholesale practice of sterilisation would remove the necessity for institutional treatment. Sterilisation would not make a defective more efficient, or lessen in any way his or her social incapacity. It is impossible to contemplate the release of the bulk of mental defectives from a sheltered environment into an unsympathetic world, there to become the prey of the unscrupulous. Sterilised or not, they must drift into crime and destitution. Institutional treatment must be maintained and extended: there can be no return to the evil days when the mentally deficient pursued a wretched existence on the streets or in the workhouse and prison. Sterilisation is to be regarded as a means whereby the accommodation in institutions and the number of mental defectives may be brought into harmony. From the point of view of economy, it is probable that institutional treatment is in the end the cheapest method of dealing with a type that must always be economically a burden. A point of some importance is that it is generally taught that the mentally deficient lead a somewhat uncontrolled sexual life. If mental defectives known to be sterilised were widespread in the community, it is not improbable that promiscuous sexual intercourse would be increased and the spread of venereal disease thereby extended. Is it not possible that vasectomy increases sexual libido? Certainly it does not diminish it.

For these reasons, it is doubtful whether sterilisation as a general policy and as a wholesale measure to be applied to all defectives can command universal approval. Undoubtedly, on economic, humanitarian, and preventive grounds, segregation as a general policy is preferable, and, if complete and continuous, it prevents propagation. No one seems to urge that such institutional inmates should be castrated, yet this is the only method of removing the sexual urge which, according to many authorities, is exaggerated in this condition and must lead to personal distress. But there is no doubt whatsoever that in special cases sterilisation is the ideal treatment. There are many defectives, for example, who are relatively stable, and for whom, after training in an institution, a suitable place can be found in the general population. In the case of such, there is only one problem—the problem of destroying their reproductive ability.

To the layman the safeguards which surround the Bill would seem entirely sufficient, but it has to be remembered that, if and when sterilisation is legalised, there will be a very considerable increase in the number of applications, from parents and others responsible for maintenance, for the discharge of patients in institutions; and, unless the very greatest care is exhibited, there will be a very real danger of the operation being extended to defectives who are quite unsuited to outside conditions, for the sole reason that someone wishes to save money. Though sterilisation will not reduce the need for further institutional accommodation, when it has been legalised, it will be used as an argument by local authorities for the non-provision of such accommodation.

From many points of view it is to be regretted that this Bill was presented before the conclusions of the presently functioning Mental Deficiency Committee of the British Medical Association have been made known. The medical profession is heavily involved in this projected scheme, and Major Church would be in a much stronger position if, in addition to the support of the Eugenics Society, he knew that he had behind him the official endorsement of medicine.

Unofficial Moments of a Great Archæologist.

A Season's Work at Ur: al-'Ubaid, Abu Shahrain (Eridu), and Elsewhere; being an Unofficial Account of the British Museum Archæological Mission to Babylonia, 1919. By Dr. H. R. Hall. Pp. xxii + 300. (London: Methuen and Co., Ltd., 1930.) 25*s.* net.

DR. HALL'S last book was published ten days after his sudden and premature death. His friends may derive some consolation, and his readers at large satisfaction, from the fact that here for the first time in his writings he has given the world a narrative which is largely of personal experience. The tragic circumstance may also excuse a reviewer who pays more attention to this aspect of the book than to the scientific.

Practically all the scientific results had indeed been more fully published elsewhere—by Hall himself in archæological journals and the British Museum official publication "Al-'Ubaid" (written in collaboration with Woolley and Gadd), pass of which are quoted at some length. Here and there he revises an opinion on a small point of detail; and in the chapters on Abu Shahrain and al-'Ubaid contributes, with some interesting plates of his own finds, a summary of the much-discussed painted pottery of the Near—and Far—East. But though almost half his space is devoted to a description of his own excavations, his main intention even here is to enable the reader to visualise the conditions and interest of his work in the field, rather than to offer him an archæological text-book.

As the full title indicates, however, there was a great deal more to this one Mesopotamian venture of Hall's than excavating alone. He was sent to report on, and take steps to safeguard, such antiquities in Iraq as he could reach; and he made the most of his mandate. He was a born traveller; scarcely a place he visited which failed to awaken some memory of stored-up knowledge; to many, unvisited before, he brought a more real acquaintance from his reading than others had got from the place itself. Allusion is the essence of his mental background—allusion which is safe from the charge of superficiality because of the amazing catholicity of his learning and the accuracy of his memory. The broken and, to-day, uninspiring arches of Koldewey's Hanging Gardens at Babylon suddenly take on the wooded appearance of the Zagros, as we follow Hall's apt comparison with the Mappin Terraces. Reaching Naṣirīyyah, which the British troops occupied after hard fighting in a July heat (1915), he recalls that though this was a " perfectly incredible time of the year for military operations . . . yet their grandfathers fought harder at Chillianwalla and Sobraon, wearing the same uniforms they would wear in London, with cross-braces constricting the chest ". A holiday spent on the Albanian coast and " a thorough acquaintance with Miss Durham's books " enabled him to talk (in Arabic) of people and places they both knew, to a Serb, who was one of the Turkish prisoners working for him at Ur. These are random examples, but typical of his attitude throughout his mission.

Hall has a very strong sense of fun, which is never suppressed for long at a time. A favourite theme is his efforts to obtain for himself, by cajoling, impudent bullying, or ' scrounging ', facilities and comforts which were not due to his rank as captain. But though he laughs at military methods, his gratitude to the several senior officers who helped him in various ways is generously expressed. He pokes fun at the large text printed in Gothic letters, the celluloid cuffs, and other relics of the German excavators, which he discovered in Koldewey's deserted headquarters at Kwairēsh. But his sallies are robbed of malice by the memory of happy times in Germany before the War—memories which he had revived during several visits in recent years.

Hall's constant reference to the kindness of officials who helped him in Iraq is matched by his frequent tributes to other workers in his own field: to Taylor and Thompson and others who had dug before him; to Woolley and Mallowan, his successors at Ur and al-'Ubaid; and to the cuneiform scholars, especially Sidney Smith and Gadd, without whom the work could not have been carried on, nor much of his book written.

Finally, the book is profusely illustrated with photographs, largely of his own taking, which in Hall's case invariably meant snap-shots. Some of his pictures are not perfect technically, but they never fail to have point or to help the text. Frequently they express his impish humour, for example, Fig. 9, called " 'Mespot' from the Tigris "; or his informal observation of things entirely outside his work, such as the photograph of the " German and L.S.W.R. locomotives " (Fig. 24); besides his delight (common to most excavators) in recording for his personal amusement every stage in his official work, even down to the transport of his boxes of antiquities (Fig. 256).

These are the qualities which will place " A Season's Work at Ur " on the shelves of specialists, to whom the bulk of the archæological material contained in it is already familiar. For the general reader the book supplies as well not only a very handy account of the history of excavation at Ur and al-'Ubaid down to 1929 and of the results thereby obtained, but also an admirable introduction to the most important ancient monuments of southern Mesopotamia.

S. R. K. GLANVILLE.

Historical Aspects of Biology.

A Short History of Biology: a General Introduction to the Study of Living Things. By Charles Singer. Pp. xxxv + 572. (Oxford: Clarendon Press; London: Oxford University Press, 1931.) 18*s*. net.

WRITERS on the history of science are too often addicted to anecdote, ancestor worship, and undue preoccupation with the blind alleys of scientific inquiry and speculation. Dr. Singer's new book has none of these defects.

He has traced the elucidation of the problems of contemporary biology to their earliest beginnings, keeping the problems rather than individuals to the forefront. Consequently, his book will provide, for many readers with no previous biological knowledge and a predilection for historical studies, an attractive introduction to the science of living matter. In adopting this course, he necessarily discloses his own views on many controversial topics. His perspective is inevitably influenced by what he regards as the most significant contemporary issues. It would therefore be easy for a reviewer to single out many passages for adverse criticism. It would also be an ungrateful act to do so. Few readers will always share all Dr. Singer's opinions. There can be no two opinions concerning Dr. Singer's erudition, the usefulness of this book, and the desirability of making its contents accessible to a wide circle of readers.

Teachers of elementary biology will welcome, in Dr. Singer's "Short History of Biology", an indispensable volume, packed with information and admirably illustrated. The style is engaging. The exposition is clear. It is divided into three parts, of which the last is the longest. The first is occupied with the history of early descriptive anatomy and natural history. It covers the period when biological knowledge embraced most of what was known of familiar terrestrial objects, before physics and chemistry had as yet emerged as experimental sciences. It includes three chapters, one devoted to Greek natural science, one dealing with the Alexandrian school and the scholastics, and one laying the foundations of the modern period in the work of the German herbalists, the "De Fabrica" of Vesalius, and the researches of Harvey. This section, in which the author pertinently discusses the relations of natural science and decorative art in the Renaissance, might have been more entertaining had Dr. Singer written with less consideration for the feelings of our eminent contemporaries who are anxious to reinstate the natural sciences in their former tutelage to ecclesiasticism. Dr. Singer dismisses the contention that the progress of natural inquiry was impeded by the growth of Christianity, though he does not overstate the favourable contrast between the world of Moslem and Christian Europe in the twelfth and thirteenth centuries. It is, of course, true that the decline of interest in natural science began long before Hypatia was butchered by the monks of St. Cyril. It is not less difficult to credit Dr. Singer's paradoxical belief that the growth of natural science was eclipsed because "the Romans were an essentially practical people". The temper and method of science are essentially practical. The seedling planted by the Greek materialists was already languishing on Greek soil before the Greek States lost their independence. Greek curiosity had been diverted into other channels, before the Roman conqueror incorporated the personnel of Greek superstition in its pantheon. Secular in its earliest beginnings, it became more and more engrossed in Persian mysticism and the mystery religions of the East. If Christianity was not chronologically the death-knell of Greek natural science, Platonism, from which Christianity borrowed the arithmetical refinements of its theology, was the signal and symbol of its decline.

In the second part, Dr. Singer deals with the historical foundations of modern biology. This section includes a discussion of the influence of Cartesian philosophy on the growth of experimental physiology, the progress of classificatory systems, the rise of comparative anatomy, the foundations of modern knowledge of the distribution of animal and plant species in space and time, and the revival of evolutionary speculation at the end of the eighteenth century. Among the more interesting features of this section are the discussions of the part played by the discovery of the microscope and the inauguration of the learned societies as factors in the separation of biological studies as a group of independent sciences outside the Aristotelian framework of the scholastic system. Chap. vii., which deals with "Distribution in Space and Time", is specially readable.

In the third part, Dr. Singer abandons the chronological method completely to trace from their beginnings in the seventeenth and eighteenth centuries the emergence of the main themes of inquiry which have occupied biological inquiry during the last seventy-five years. Separate chapters are devoted to the cell doctrine, biogenesis, the chemistry of the body, the process of development, sex, heredity; and the history of the nervous reflex is dealt with in the chapter entitled "The Relativity of Functions". Here Dr. Singer writes with a very evident bias towards the introspectionist point of view. Whether he has maintained his determination to avoid undue attention to unprofitable lines of inquiry is a matter for doubt. Time alone will show whether the writings of Lloyd Morgan deserve prominence in a history of science, except as evidence of the survival of Aristotelianism in the machine age.

In its plan and method Part 3 is the best section in the book. The separate paths which have been followed in the attempt to elucidate the main contemporary themes of biology do not as yet coalesce. To treat biology in the latter half of the nineteenth century as a single unit of human inquiry would have been disastrous. Dr. Singer has felt compelled to introduce much that is topical in this section, to clear the ground for the reader who is not a highly trained biologist. Had he done otherwise he would certainly have been less intelligible to many who, it is to be hoped, will read his book. On the other hand, those who are trained biologists will be disappointed to find that the historical aspect of this section is rather overshadowed by the exposition of elementary principles and all too familiar facts. Dr. Singer can atone for this shortcoming by writing another book more especially for the specialist. The book he has written contains much matter which will be suggestive and instructive to many who are biologists, and it should kindle the interest of still more who are not biologists.

It may be hoped that this book will add to the growing dissatisfaction which is felt towards present methods of teaching elementary biology in Great Britain, where the 'type system' still discourages many students from pursuing the study of animal life. Dr. Singer perhaps goes rather too far in subscribing to the doctrine that "l'histoire de la science c'est la science même". It is quite possible to understand the principle of segregation, to use it as an instrument to interpret and predict the results of breeding experiments, and to extend its scope without knowing anything about the studies which an Austrian abbé conducted in a quiet monastery garden seventy years ago. It is unlikely that the progress of modern genetics would have been impeded if de Vries, Correns, and Tschermak had remained ignorant of the fact that their discoveries had been forestalled forty years earlier. It is also true that no one can contribute to an intelligible exposition of the present status of the evolutionary hypothesis if he is unfamiliar with the metamorphosis which the word 'selection' has undergone, as it has passed in turn through the hands of Darwin and Wallace, Weismann and Galton, Morgan and J. B. S. Haldane. Without attention to its history the teaching of science provides a poor equipment for the understanding of a civilisation which owes its special peculiarities to the utilisation of scientific knowledge. The history of science is the major part of a philosophy attuned to the civilisation to which we ourselves belong.

Dr. Singer himself believes that there is a legitimate field for philosophy transcending the synthesis of all scientific knowledge. Those who question the usefulness of applying the term 'knowledge' to anything which lies outside the scope of mathematics and experimental science may look forward to a time when the subject he has done much to advance will enjoy a greater share of public esteem than he would claim for it. In the newer secular universities, departments of the history and method of science staffed by workers trained in the historical and natural sciences might well displace the teaching of a subject whose only *raison d'être* is its historical rôle as the rationale of a discredited supernaturalism.

Lancelot Hogben.

Physics for Students.

(1) *Physical Principles of Electricity and Magnetism.* By Prof. R. W. Pohl. Authorised translation by Winifred M. Deans. Pp. xi + 356. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 17*s.* 6*d.* net.

(2) *A Survey of Physics for College Students.* By Prof. Frederick A. Saunders. Pp. x + 635. (New York: Henry Holt and Co., 1930.) 3.75 dollars.

(3) *General Physics.* By Prof. Wm. S. Franklin and Prof. G. E. Grantham. Pp. xvi + 705. (Lancaster, Penn.: Franklin and Charles, 1930.) 4 dollars.

(4) *Intermediate Physics.* By Dr. R. A. Houstoun. Pp. xviii + 638. (London, New York and Toronto: Longmans and Co., Ltd., 1930.) 10*s.* 6*d.*

(1) AN unqualified welcome can be given to this excellent translation of the second edition of Prof. Pohl's book, of which the original edition has already received appreciative notice in Nature. Here is given, with a completeness and mastery unapproached in any English work of the kind known to the reviewer, a lucid and systematic account of the physical principles of electricity and magnetism. While the treatment is everywhere didactic, it is shown how the ideas involved and their development are always based on experiment, Prof. Pohl's ingenuity and resource in this direction being most notable. There is very little reference to persons or history, the closely knit argument being almost completely untrammelled by tradition and unhampered by customary modes of presentation; and while the mathematics used is almost negligible, the strict logic and quantitative treatment make the presentation very thorough, and

the wealth of illustration and clarity of statement result in a wholly delightful book.

(2) Prof. Saunders' survey also produces a very favourable impression. Without being superficial, or straining for effect, the author has succeeded in giving an account of the subject matter of physics covering a surprisingly wide field, the writing being accurate and restrained, but never lacking in interest. The scope of the book may be realised when it is mentioned that, to take only a few haphazard examples, the mass spectrograph and isotopes, quanta, the Raman and Compton effects, spectrum series, atmospheric electricity and cosmic rays, acoustics of buildings, solar radiation, and Bernouilli's principle are among the many matters dealt with.

The author does not lose sight of the essence of physics as a coherent and systematic body of thought; indeed, the distinction of his work lies in the way this is apparent, while at the same time up-to-date practical applications, theory, and research all find their place. The clear diagrams and well-chosen illustrations merit a word of commendation. It is a pleasure to find a book of this kind which, instead of being a heterogeneous compilation, either childish or incomprehensible, is such an admirable example of what this sort of thing should be.

(3) Profs. Franklin and Grantham have prepared an elementary treatise, most of the 694 pages of which are taken up with work of a standard nature, although more advanced and comparatively recent ideas are incorporated—unfortunately, not always too clearly. The volume is interspersed with short essays or paragraphs of a general character with titles such as "The Wisdom of Ignorance", "The Illusion of Activity", "Wave Mechanics", and "The Modern Idolatry", which do not appear to add materially to the value of the book.

Features worthy of mention are the liberal sprinkling of problems in connexion with the text, and the analogy of electrostatic with electromagnetic quantities and that existing between the latter and mechanical units. The book is primarily intended for American students; whether it has any particular value in Great Britain is doubtful.

(4) With the completion of the section on sound, Dr. Houstoun has been able to collect the various parts of his "Intermediate Physics" into one volume. The subject matter is presented in the direct, clear manner which one has learned to associate with the author, and a reliable, convenient textbook is thus made available.

Short Reviews.

A Brief History of Medicine in Massachusetts. By Dr. Henry R. Viets. Pp. xii + 194 + 8 plates. (Boston and New York: Houghton Mifflin Co., 1930.) 4 dollars.

THIS work, which is issued on the occasion of the tercentenary celebration of the settling of the Massachusetts Bay Colony and the one hundred and fiftieth anniversary of the founding of the Massachusetts Medical Society, is divided into seven chapters. The first is an introduction, in which a sketch is given of contemporary medicine in Europe in the sixteenth and seventeenth centuries. The second chapter deals with the colonial period dating from the landing of the pilgrims from England on Dec. 21, 1620, to the end of the seventeenth century, during which the bond between the clergy and the medical profession gradually became severed. In the third chapter, which is concerned with the eighteenth century to the American Revolution in 1775, the author shows that medicine in Massachusetts during that period was characterised by severe epidemics of small-pox, partially controlled by the introduction of inoculation in 1721, strict enforcement of quarantine in the fort of Boston, improvement in the tone of medical practice, the establishment of a medical society, the appearance of sporadic medical literature, and the divorce of medicine from the influence of the ministers.

In the fourth chapter, the effects of the American Revolution and the formation of the Massachusetts Medical Society and the Harvard Medical School are described. The fifth chapter is concerned with the early nineteenth century, during which Benjamin Waterhouse introduced vaccination into the United States, the Massachusetts General Hospital and *Boston Medical and Surgical Journal* were founded, Jacob Bigelow published his work on self-limited diseases, and Oliver Wendell Holmes his classical paper on puerperal fever. The sixth chapter is devoted to an account of the discovery in 1846 of ether anæsthesia by the dentist, W. T. G. Morton, described by Dr. Viets as the most important advance in medicine made in the United States. The last chapter contains a sketch of the contributions by Boston men to medicine and surgery from 1847 to the present day.

The work is illustrated by several portraits and a list of references is appended.

Environment and Plant Development. Being "Klima und Boden in ihrer Wirkung auf das Pflanzenleben". By Prof. Dr. Henrik Lundegårdh. Translated and edited from the second German edition by Eric Ashby. Pp. xii + 330 + 8 plates. (London: Edward Arnold and Co., 1931.) 24*s.* net.

THE keynote of this book is the author's invitation to the student to go out into the field and to study the living plant in its natural surroundings as well as the natural environment of the plant. He pays full tribute to investigations which have been conducted in the laboratory, but he carries laboratory research in plant physiology, with its many limitations, into the field, where the life processes of plants, though more difficult to study, can be investigated under entirely natural conditions. He emphasises that records obtained of a plant's behaviour at any given time or at stated intervals do not reveal the many fluctuations which the plant undergoes during the whole period of the day, for plant environments experience more widely different ranges and variations of climate than those recorded by the usual meteorological instruments.

Suggestive ideas, often based on isolated investigations and experiments, indicate to the field ecologist the many avenues of research still awaiting him. The interpretations suggested for many well-known phenomena will prove of considerable interest and value to the botanist, horticulturist, agriculturist, and forester, and illustrate the part that botany plays as a basic science for all these forms of study of plant life.

The last chapter, devoted to principles of experimental ecology, contains an interesting and suggestive "Survey of Adaptation Forms": a contribution to the classification of plants on ecological principles. The field botanist is left to develop this scheme and complete the 'key' to plant life in relation to ecological characters. The author closes with the remark, which by now will have been impressed upon his reader, that "the detailed ecological analysis of an association is, however, an extremely troublesome and tedious undertaking".

The translation has been rendered into simple language which enables the arguments to be followed readily by any student of botany.

Cancer and Scientific Research. By Dr. Barbara Holmes. (Sheldon Books of Popular Science.) Pp. 160. (London: The Sheldon Press; New York and Toronto: The Macmillan Co., 1931.) 3*s*. 6*d*. net.

ACTIVE research into the cause of cancer is now running mainly along two lines. Laboratory workers are particularly concerned with the experimental production of cancer by tar and other similar irritating agents, and with the fowl tumours which may be transmitted from bird to bird by an ultramicroscopic agent. Statisticians and hygienists, on the other hand, are attentively and fruitfully examining the relation between modes and habits of life and the occurrence of malignant tumours. Particularly encouraging is the fact that these two methods of approach have in recent years converged to the common conclusion that much cancer is due to external influences rather than to any inherent vice in the body, and should therefore be preventable.

We do not know of any short semi-popular publication in which the important facts—and some of the theories—are set out so plainly as they are here, and with as good an instinct for grain rather than chaff. The common significance of the human and animal experience is well brought out. Dr. Holmes wisely confines herself to the causes of cancer, and scarcely mentions treatment. We can commend her book to biologists in general even more heartily than her father does in the preface.

A Brief Introduction to the Use of Beilstein's Handbuch der organischen Chemie. By Prof. Ernest Hamlin Huntress. Pp. viii + 35. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 5*s*. net.

THIS is an interesting booklet designed to help the young student in mastering the intricate system of classification used in the last edition of Beilstein's "Handbuch". A very comprehensive account of this is given at the beginning of vol. 1 of the "Handbuch"; but the system is naturally so complicated and difficult to understand that properly to assimilate it requires a better knowledge of German than most young students possess. Notwithstanding the excellent compendia that exist, Beilstein is still the best and most used source of information on organic compounds, and it is essential that anyone intending to specialise in organic chemistry should be able to find his way in it easily and rapidly.

The booklet under review gives a very concise, clear, and intelligible account of the system of classification of the alicyclic and homocyclic divisions, and concludes with a number of examples to illustrate the fundamental points involved.

The printing is good and is singularly free from typographical errors. Its sole disadvantage is the price, which is high for a 35-page booklet.

The Monadology of Leibniz: with an Introduction, Commentary and Supplementary Essays. By Dr. Herbert Wildon Carr. Pp. ix + 213. (London: The Favil Press, 1930.) 10*s*. net.

THE popularity of Leibniz in recent years gives an added interest to this new critical edition of the masterly epitome of the great philosopher's views. A running commentary accompanies each paragraph of Prof. Carr's translation, and illuminates the condensed thought of the "Monadology". The elucidations of Leibniz himself on the origin and meaning of the theory of monads, on the reform of the ontological argument, on the definition of matter, on the nature of free-will and the theory of pre-established harmony, together with Prof. Carr's supplementary essays on the monadology, are a useful help to the understanding of this work, which is but a small part of Leibniz's philosophy. T. G.

How You Work: an Introduction to the Human Body. By Dr. Isabel Wilson. Pp. xi + 178. (London: Gerald Howe, Ltd., 1930.) 3*s*. 6*d*. net.

THIS delightful little book is so attractively written and couched in such simple language that no child ought to be denied the opportunity of hearing, from teacher or parent, about the working of its little body. There can be no better exercise for the attainment of human understanding and happiness than that of starting to think biologically at an early age.

Helium and its Properties.*

By the Right Hon. LORD RUTHERFORD, O.M., F.R.S.

THE history of the discovery of helium presents some features of unusual dramatic interest. During an eclipse in 1868, Jansen and Lockyer noticed that the visual spectrum of the sun's chromosphere showed a bright yellow line of unknown origin. Later it was found that this line and others that accompanied it appeared not only in the sun, but also in many of the stars. Lockyer suggested that these lines were due to an undiscovered element, to which he gave the name helium.

Shortly after the discovery of argon, Sir Henry Miers sent a letter (Feb. 1, 1895) to Ramsay pointing out that the American analyst Hillebrande had observed that a considerable quantity of gas, supposed to be nitrogen, was liberated by solution of certain minerals containing uranium. Miers suggested that the gas might prove to be argon and not nitrogen. Following his suggestion, Ramsay purchased about a gram of the mineral cleveite from a dealer for three shillings and sixpence and proceeded to purify the gases evolved and to examine their spectra. A number of new lines were observed and a spectrum tube containing the new gas temporarily called crypton by Ramsay was sent to Sir William Crookes for a detailed study of its spectrum. Crookes reported tersely, "Crypton is Helium ; come and see it". Less than two months had elapsed from the receipt of Miers's letter to the announcement in the Paris Academy of Sciences, on March 26, 1895, of the discovery of helium on the earth—a discovery of profound significance to the development of physics. It was soon shown that helium is a monatomic gas of density about twice that of hydrogen and of atomic weight 4. We now know that it is the first of that remarkable group of inert monatomic gases, namely, helium, neon, argon, krypton, xenon, and the radioactive emanations, which have played such an important part in helping to fix the arrangements of the electrons in the outer atom.

In 1903, Ramsay and Soddy found that helium was produced by the transformation of radium, and, as a result of a series of researches, Rutherford showed that the α-particles which are ejected with great velocity from radioactive atoms are identical with helium nuclei. It is probable that the greater part, if not all, of the helium found in the earth and in the natural gases escaping from the earth owes its origin to the α-particles expelled from the radioactive elements during their transformation in the earth's crust.

It now seems clear that the helium nucleus of resultant charge 2 is remarkably stable and is in some way built up by the combination of four protons and two electrons. The loss of mass in this combination shows that a very large amount of energy, probably in the form of penetrating γ-rays, is emitted during the process. It can be calculated that the energy released in the formation of one pound of helium from hydrogen corresponds to the energy liberated in the complete combustion of 10,000 tons of coal. There can be no doubt that helium is formed from hydrogen under some, as yet unknown, conditions in the stellar system. However, it has not yet been found possible to produce helium from hydrogen under laboratory conditions. Millikan claims that the absorbable part of the cosmic rays must be attributed to the radiation emitted in the formation of helium in the depths of space.

The α-particle or helium nucleus has proved of great importance in extending our knowledge of the structure of nuclei, and it is now believed that the nuclei of the heavier elements are composed mainly of α-particles and electrons, although a few free protons may also be present. The bombardment of light elements by swift α-particles has given us the first definite proof of the transformation of some of the ordinary elements by artifical methods.

Helium is the most difficult of all gases to produce in liquid form. This was first accomplished by the late Prof. Kamerlingh Onnes in his laboratory at Leyden in 1908 by using liquid hydrogen as a cooling agent. Helium liquefies at a temperature of about 4° absolute, and is a clear colourless liquid of density about 0·15. In recent years, by using helium under pressure, Prof. Keesom, of Leyden, has succeeded in solidifying helium. By the evaporation of liquid helium at low pressure, temperatures so low as 1° absolute have been obtained.

Liquid helium thus provides a suitable method for the study of the effect of low temperatures on the properties of matter. One of the most striking observations is that certain metals become superconductors at such low temperatures and show little if any resistance to the passage of an electrical current. Several cryogenic laboratories have been instituted for the study of the effects of low temperatures on matter. Apart from the well-known and well-equipped laboratory at Leyden, Prof. J. C. McLennan liquefied helium in the University of Toronto in 1923, while in 1925 a similar department was instituted in the Reichsanstalt, Berlin. Researches in the properties of matter at the lowest possible temperatures have already added widely to our knowledge in a number of important directions.

Helium is present in our atmosphere in small quantity, about one part in 185,000 by volume. In the early days, most of the helium used for experimental purposes was obtained by heating radioactive minerals and particularly the mineral thorianite from Ceylon. It was also found that helium is often present in considerable quantity in the gases escaping from hot springs and the natural gases from the earth's crust.

In 1914, Sir Richard Threlfall suggested to the

---

* Abstract of the Friday evening discourse delivered at the Royal Institution on March 27.

Board of Inventions of the Admiralty that, on account of its lightness and non-inflammability, helium might prove of great service for balloons and airships. Prof. J. C. McLennan was asked to initiate experiments to see whether helium could be separated in quantity from the natural gases escaping from the earth in certain districts of Canada which were known to contain about 1 per cent of helium by volume. Arrangements were made on a semi-commercial scale to purify the helium by liquefying the methane and other gases present. The impure helium was concentrated in the non-liquefying portion. In this way, many thousands of cubic feet of helium were prepared and transported in cylinders at high pressure. About the same time, the Bureau of Mines of the U.S.A. began similar experiments on a large scale, using the natural gases of Texas, which are rich in helium. Large quantities of helium were separated by liquefaction methods, and the cost of the helium was found to be sufficiently low to use it in airships in the place of hydrogen. Apart from the cost of transport, the expense of separation of helium decreases with the concentration of the helium in the natural gases. The commercial prospects of the use of helium in airships and other purposes have led to a search for rich concentrations of helium.

While most natural gases contain less than 1 per cent of helium, much richer mixtures have been recently found by boring. One source in Grand County, Utah, has a helium content of 7 per cent. Another was found in Colorado yielding as high as 8 per cent. The gas appears at a depth of about 950 feet in what is known as the Wingate sand. The Helium Company has erected a plant at Thatcher, Colorado, for purification of the helium obtained from this source. Analysis shows that the gas contains 15 per cent carbon dioxide, 8 per cent helium, 1·75 per cent methane, and the rest nitrogen. The plant installed has a capacity of about 600,000 cubic feet of the gas per day, corresponding to a possible annual production of 12 million cubic feet of helium. With such a rich helium mixture, the cost of separation should be much less than in the plants treating the natural gases of much lower helium content.

It is possible that similar rich concentrations may be found on the eastern slopes of the Rocky Mountains in Canada. A small gas field was found a few years ago not far from Toronto which had a content of 0·8 per cent helium. The rights of those wells have been secured for the University of Toronto in order to have an ample supply of helium for cryogenic experiments in the laboratories.

At the time of its discovery, helium was considered to be a rare gas and a litre of helium was a precious possession. The helium originally employed by Kamerlingh Onnes for the liquefaction of helium was painfully obtained by heating radioactive minerals. This is in striking contrast to the position to-day, when the annual production of helium is measured by millions of cubic feet, and where sufficient quantity will be available at a comparatively low cost for filling several large airships now in course of construction.

A. M. Liapounov, 1857–1918.

By A. J. PRESSLAND.

FROM time to time, French versions of the writings of A. M. Liapounov have become available to the scientific public; but the obituary notice in the *Proceedings* of the Academy of Sciences in Leningrad (1919, p. 367, by Stekloff), and other papers, are in Russian. Quite recently the Academy has published two brochures, one a biography and the other a general survey of Liapounov's work on Chebichev's problem, and the following is a digest of this material.

A. M. Liapounov, the eldest son of M. V. Liapounov and a grandson of V. A. Liapounov, registrar of the University of Kazan, was born on May 25, 1857. Six of his immediate kinsmen attained to academic eminence. His father, an astronomer of repute, died in 1868, leaving a young family. So the boy was brought up for a time by a married aunt, in whose house he increased his acquaintance with people of intellectual distinction. In 1870 he entered the third class of the gymnasium of Nishni-Novgorod, where he was taught Latin, Greek, and elementary science. He read widely, Buckle, Draper, Humboldt, Réclus, and Karl Ritter being his favourite authors, and he developed a love for exact science. The national idealism that was then popular did not appeal to him, but he was attracted by the study of economics and the theory of the struggle for existence.

In 1876 Liapounov passed out of the gymnasium with the highest distinction and matriculated at St. Petersburg, where at first he attended the lectures of Mendeléeff, which he soon forsook for those of Chebichev. To the latter is due the inspiration of Liapounov's researches. Chebichev laid stress on *Anschauung* and *Realien*, holding that research work was valuable only when it lent itself to application, and theory useful only when it emerged from a consideration of particular cases.

Chebichev directed Liapounov to the problem of determining the free surface of a liquid gravitational mass that was rotating about an axis. He had already proposed the problem to prominent students such as Zolotarev and Sophia Kovalevskaya, but no one of them seems to have made noteworthy progress. The problem has a long history. Newton noted that an ellipsoid of revolution can be a surface of equilibrium, but Maclaurin was the first to give it serious consideration; on this account an ellipsoid of revolution which is a form of equilibrium is called an ellipsoid of Maclaurin. D'Alembert showed that for every angular velocity less than a given limit there were two Maclaurin ellipsoids, each compressed in the direction of the axis of rotation. Laplace showed that, as the moment of angular momentum increased, the smallest axis of the ellipsoid decreased until the angular velocity reached its maximum, after which the angular velocity decreased to zero and the ellipsoid flattened out, becoming ultimately a thin disc of infinitely large radius. Hence for each value of the angular velocity there will be two Maclaurin ellipsoids, and Lagrange was of the opinion that these were the only two possible ellipsoids of equilibrium. But Jacobi proved that the ellipsoid with three unequal axes was also a possible form.

Jacobi's solution was examined by Meyer and Liouville. The latter showed that in certain cases a long thin ellipsoidal spindle might be obtained, the largest axis of which increased without limit and the other two approached zero in magnitude and unity in ratio. So it can be proved that, within certain limits of the value of the angular velocity, there may be three ellipsoids of equilibrium—two of Maclaurin and one of Jacobi; within other limits, two only each of Maclaurin, and the latter may coincide giving one only, of Maclaurin.

Chebichev told Liapounov that easy but novel problems which could be solved by well-known methods were of no value in testing the powers of a young research student. Such a student required something that presented obvious difficulties. So the problem was enunciated thus: "It is known that for certain values of the angular velocity the ellipsoidal form no longer serves as a surface of equilibrium for rotating homogeneous liquids. Does it change into some new form of equilibrium which, for small increments of angular velocity, differs but little from an ellipsoid?"

Domestic misfortune interrupted Liapounov's university career; but he won a university prize, and after graduation chose as the subject of his M.A. dissertation "Some Particular Aspects of Chebichev's Problem", which he defended before a board of which Bobilev and Korken were members. In 1885 he was recognised as a *privat-dozent* and was preparing to lecture on the theory of potential when he received a call to the chair of mathematics at Kharkov. His new duties, which were increased by work at the local technical institute, were so strenuous that he had to defer the presentation of his dissertation for the doctorate, for five years. The subject was "Some General Aspects of Chebichev's Problem". These two dissertations were translated into French and published by Davaux in 1904, 1908.[1]

In 1901 Liapounov was elected a member of the Academy of Sciences at St. Petersburg and thus secured the leisure and the freedom from financial cares that enabled him to resume his work on the problem. He soon discovered that to the first approximation there were no new forms and that a second approximation was hard to obtain. In his M.A. dissertation he had discussed the stability of the ellipsoids of Maclaurin and Jacobi and had found that when Maclaurin's became unstable they changed into those of Jacobi, and that the latter when they became unstable appeared to change into a new figure having algebraic surfaces of the third degree (Poincaré's pear-shaped figure).

Within a year of the publication of the M.A. thesis Poincaré mentioned in *Comptes rendus* that he had been in correspondence with Lord Kelvin on the subject. Lord Kelvin had arrived at results but had given no proofs. Poincaré reached the same results as Liapounov but by less stringent methods, and Poincaré assumed that the figures sought really existed. In answer to Liapounov's inquiry, Poincaré replied that he had not proceeded beyond the first approximation and that the methods of successive approximations did not provide a proof of the existence of the figures, since the difficulty of finding a second approximation was insurmountable. His assertion, that the figures sought existed, seemed to Liapounov to be based on intuition, and when Poincaré's memoir appeared in *Acta Mathematica*, Liapounov was dissatisfied with it.

When Liapounov, twenty years later, resumed consideration of the problem, he soon found where the difficulty of the second approximation lay. Poincaré and Liapounov, when seeking the new figure that differed but little from the given ellipsoid, had compared it with the given ellipsoid. Liapounov now overcame the difficulty by introducing an ellipsoid confocal with the given one and passing through that point of the surface sought at which the potential of the attracting liquid is under consideration. By this means Liapounov easily obtained approximations to any given order and was able to prove the series convergent. Thus Liapounov was able to give a rigorous proof of the existence of those forms of equilibrium already known and to show that there were no intermediate forms.

There are other special solutions of the general problem. Poincaré and Sophia Kovalevskaya have treated an annular form such that the section of it made by a plane through the axis of rotation is approximately an ellipse. There are also cylindrical forms of equilibrium which provide material for mathematical problems. Liapounov directed attention to the case of two liquid masses separated from one another and each rotating round an axis, which passes through the common centre of gravity and is perpendicular to the line joining the centres of gravity of the two separate masses, and found that when they were sufficiently far apart their surfaces of equilibrium differed but little from ellipsoids; and he proved that for homogeneous liquid the pear-shaped figure is unstable.

This result is at variance with the results obtained by Poincaré and Darwin, each of whom found difficulty in obtaining a second approximation. Poincaré found one by a special process which yielded no further approximations. Darwin adopted the result, which supported his theory of cosmogony. Liapounov, however, declared that Poincaré's methods were not rigorous, since they were based on approximate formulæ, whereas his own were obtained by exact formulæ.

The stumbling-block had been an expansion of the potential due to Lagrange and Laplace. No proof had been given that this expansion was admissible. Liapounov replaced it by a new expansion having a smaller parameter, established the admissibility of the new expansion, applied the methods of successive approximations, showed how to find these approximations to any required order, proved that his approximations were convergent, and generalised his investigations.

Liapounov's papers on Chebichev's problem are contained in four volumes published between 1906 and 1914, written in French and extending to 768 folio pages. It is understood that Liapounov left a large amount of manuscript which will be published when circumstances permit. This remark applies also to the papers of Leonard Euler. In 1902, the Academy of Sciences proposed to mark the bicentenary of the birth of Euler (1907) by the issue of a complete edition of his works. A committee consisting of A. A. Markov, B. B. Galitzin, and A. M. Liapounov was appointed to deal with the matter. It is possible that the latter has left papers dealing with the subject.

It is painful to describe the last days of Liapounov. Russia was involved in political and social turmoil, and it was at one time feared that Liapounov might suffer like Lavoisier. This fear happily was unfounded. His wife was attacked by tuberculosis and he was threatened with cataract. They went to Odessa in search of health, and there his wife died. A few days later, on Nov. 3, 1918, he died in Leningrad as the result of a voluntary act.

Two Historic Electric Power Stations.

AT an ordinary general meeting of the Newcomen Society held in London on April 15, and at the seventh annual meeting of the American members held in New York on April 16, two papers were presented dealing with two historic electric power houses. One of the papers was by Mr. G. A. Orrok and dealt with the Pearl Street station in New York, the first central station in the world; the other was by Col. R. E. B. Crompton and gave a history of the first installation of house-to-house electric supply in England, the power house of which was described as "the parent generating station of Great Britain". It was the invention of the incandescent light, the perfecting of the dynamo, and the invention of the multiple arc system, with its corollary in the feeder system and three-wire system, which brought the central station into being as a means of furnishing a means of transmitting light, heat, and power in any amount and to such distances as might be required. In the early 'eighties, many private installations of electric lighting plant were laid down, and generating plant was supplied to individual buildings and ships, but the two stations referred to at the meeting of the Newcomen Society were the first stations in the United States and England respectively to supply electric current to customers in the same way that gas and water had been supplied.

The Pearl Street station was due to the genius of Edison, from whose note-books of 1878 and 1879 can be gathered some of his earliest ideas on electric power generation and distribution. The Edison Electric Light Co., the parent company of all the Edison companies, was incorporated early in 1880, and the Edison Electric Illuminating Co. of New York, the local company, held its first meeting on Dec. 20, 1880.

To the latter belongs the credit of erecting the Pearl Street station, which began operations on Sept. 4, 1882, and by the end of 1883 had 455 customers and more than 11,000 lamps installed. The original plant consisted of four Babcock and Wilcox boilers of 200 h.p. each, supplying steam at 120 lb. pressure to Porter-Allen high-speed engines of 125 h.p. each, directly coupled to the famous 'Jumbo' dynamos. As the station was half a mile from the river, it was a non-condensing station and the coal consumption at first was about 10 lb. per kw. hour. A serious fire on Jan. 7, 1890, interfered with its operation for a time, and five years later this pioneer station was closed down and the property disposed of.

Many interesting particulars of the electrical equipment of the station were given by Mr. Orrok. From the dynamo brushes the current was led by round copper bars to spring-controlled switches, the design of which was taken from the short-circuiting switch under the telegraph key. The station bus bars were fixed to wooden insulators bolted to the walls. There were neither voltmeters nor ammeters, as such things had not been invented.

Crude as many of the devices were, they met the situation and enabled central station companies to do business. Referring especially to Edison's chemical meter, in which each unit of current invariably removed a definite amount of zinc from one metal plate to another, Dr. Orrok said: "Was there ever a more beautiful combination of parts—each dependent on a simple physical or chemical law—than was presented in this ingenious commercial device for translating first the lamp-hour, then the ampere-hour, and finally the kilowatt-hour values into dollars and cents? . . . It is no exaggeration to say that no single device in the whole system did more to lay the solid foundation for the commercial and financial success of the Edison stations from the first than the chemical meter."

The first central station in Great Britain, dealt with in Col. R. E. B. Crompton's paper, was situated in Kensington and was erected by the Kensington Court Company, afterwards the Kensington and Knightsbridge Company, started by Col. Crompton to supply electricity to the houses they erected on a site which had been cleared by the company promoter, Baron Grant, but which had passed into the hands of the Land Securities Company.

In the generating station were installed two

Babcock and Wilcox boilers, supplying steam to seven generating sets. The dynamos were coupled directly to Willans central-valve high-speed engines. Three sets were designed to give 500 amp. at 100 volts and four sets 500 amp. at 200 volts. Vibration troubles were avoided by fixing the sets to massive concrete foundations kept clear of the buildings.

Meters were rented to customers and the current was distributed by bare copper strip conductors fixed to porcelain insulators in subways in the streets. To ensure continuity of supply, a large battery of accumulators was installed. Current was supplied to a certain number of houses in 1886, by 1887 the company was making a profit, and later on another station was erected at Chapel Place, Knightsbridge. As the demand increased, a still larger plant was built at Wood Lane, Shepherd's Bush. This was put into operation in 1901, and soon afterwards the original steam plants in Kensington and Knightsbridge were shut down.

Obituary.

MAJOR T. F. CHIPP.

IN writing an account of the life and labours of those who truly may be said "to have finished their course", after having enjoyed the allotted span and seen the fruit of their work, there is, despite the sadness, an element of satisfaction and the fitness of things. But in the case of one of much promise, suddenly removed in the prime of life and with every prospect of a distinguished and useful career in the future, feelings of grief and sadness predominate and render the task of writing any adequate tribute both painful and difficult.

The tragically sudden death of Major Thomas Ford Chipp, assistant director, Royal Botanic Gardens, Kew, is such a case. Born on Jan. 1, 1886, he died on Sunday evening, June 28, at 9 P.M., shortly after returning to his house. Chipp was thus in the prime of life, tall, strong, vigorous, always happy and cheerful, filled with enthusiasm for his work, and deeply interested in the many duties which fall to the lot of Kew's assistant director. Through his varied colonial and War experiences he had gained a wide knowledge of men and affairs, and in addition he was a man of sound judgment and commendable tact; he was endowed with a very pleasant personality, which, during his nearly nine years' service at Kew as assistant director, had endeared him not only to his scientific colleagues but also to all the student gardeners and the whole of the Kew staff. In the larger botanical world both at home and abroad he was highly esteemed, and this was clear at the International Botanical Congress held last year at Cambridge, and is also borne out by the many letters which have reached Kew. The untimely death of a man of his calibre and powers, when men of this type are all too rare, is a greater loss than Kew has ever before been called upon to bear. His death will be equally a very severe loss to the botanical work of the Empire centred at Kew.

Chipp was the son of Edward Thomas Chipp, chief constable of Gloucester. He received his early education at the Royal Masonic School, Bushey, and there he quickly developed his taste for natural history and served as secretary to the school natural history society. This inclination towards science led him to look to horticulture for a career, and, after a period of service in the gardens of Syon House, he entered Kew in 1906 as a student gardener. After a few months in this capacity, he was selected, owing to his marked ability, for one of the temporary technical assistant posts in the herbarium, where he remained until 1908. During this period he prepared himself, in his spare time and with very limited means, for the B.Sc. examination, University of London, which he passed in 1909 with honours in botany. He then received an appointment as demonstrator in botany at Birkbeck College, and in 1910 was appointed an assistant conservator of forests in the Gold Coast. Before proceeding to West Africa, he spent a year studying forestry in Germany and the Federated Malay States.

In 1914, Chipp was appointed assistant director of the Botanic Gardens at Singapore, but the War starting while he was in England *en route* for the Straits Settlements, he at once sought permission to rejoin his territorial regiment, the 8th Middlesex, in which he had held the rank of captain. With his regiment he proceeded to Gibraltar and afterwards to France, where he served continuously until 1919, being ultimately attached to the staff with the rank of major, and was awarded the Military Cross. In 1919 he went to Singapore to take up the post of assistant director to which he had been appointed five years earlier.

Chipp's good work while assistant conservator of forests in the Gold Coast had been duly noted, and in 1921 he accepted the invitation from the Gold Coast to be deputy conservator of forests in the colony. His career both at home and in the colonial service had naturally also been closely followed at Kew with interest and appreciation, and on the retirement of Sir David Prain in 1922 and the promotion of the present director, Major Chipp was invited to occupy the vacant post of assistant director of the Royal Botanic Gardens, Kew, and assumed office on Aug. 1, 1922.

Chipp was never idle, and his first scientific contribution of importance, "A Revision of the Genus *Codonopsis*", was made to the Linnean Society of London in March 1908. His university studies and forestry training during the next few years prevented him from carrying out any original work of importance, but on reaching the Gold Coast he soon produced the very useful "List of Trees, Shrubs and Climbers of the Gold Coast, Ashanti and the Northern Territories", in 1913, and a similar "List of the Herbaceous Plants and Under Shrubs" in the following year. Shortly after his return to the Gold Coast, in 1921, he published a "Forest Officers' Handbook of the Gold Coast, etc." (1922), which won him the London degree of Ph.D. The War period naturally precluded any possibility of scientific activities, but it is characteristic of Chipp's unbounded energy that, directly he took up his duties at Singapore, he set to work and contributed many articles to the *Gardens Bulletin* of the Straits Settlements; among the more important of these are his papers on "The Fungi of the Malay Peninsula".

When he became assistant director at Kew, in 1922, Chipp used any spare moments for carrying on the researches he had initiated during his second period of service in West Africa, and published some useful papers in the *Kew Bulletin*. He became a recognised authority on vegetation studies, and was honorary secretary of the British Empire Vegetation Committee. In this connexion he edited, with Prof. A. G. Tansley, the very valuable book, "Aims and Methods in the Study of Vegetation" (1926), which is recognised as the leading book on the subject. To this book he contributed the chapter relating to the tropical countries. As honorary secretary of this Committee, he devoted much labour to reading, digesting, and reviewing numerous publications relating to the vegetation and ecology of the Empire. His more recent book, "The Gold Coast Forest: a Study in Synecology", published in 1927, is a valuable contribution on original lines. This work formed his thesis for the degree of D.Sc.

At the beginning of 1919, Chipp was sent to Cyprus and the Sudan by the director of Kew, on the invitation of the respective Governments, and the reports on his visits were of great value and highly appreciated. While in the Sudan, he was able to ascend the scarcely known Imatong Mountains, on the Uganda border, making a careful study of the flora and bringing home large collections. An account of the botany of the region was published in the *Kew Bulletin* in 1929, and a more general account of his tour, entitled "Forests and Plants of the Anglo-Egyptian Sudan", appeared in the *Geographical Journal* for February 1930.

Chipp was co-secretary, with Mr. F. T. Brooks, of the Fifth International Botanical Congress, held at Cambridge last year. The organisation of this large Congress and the subsequent editing of the various reports entailed a vast amount of labour for the secretaries, and the perfection of the arrangements, and the smoothness with which the heavy programme was carried through, showed again the care and thoroughness which appeared in all Chipp's work. The preparation and publication of a new International Address-book of Botanists, decided upon by the Congress, was entrusted to an international committee consisting of Major Chipp, Prof. Diels of Berlin, and Dr. Merrill of New York. A great deal of the work of collecting information, and all the labour of final collation and the arrangements for publication, had been almost completed by Chipp with his usual ability just before his death, and the work is now in the printer's hands.

Early last year, after attending the French Government celebrations in Algeria, Chipp was invited to accompany Mrs. MacIver's expedition into the Central Sahara, and made a careful study of the vegetation; his account of the scientific work of the expedition will be found in the August number of the *Geographical Journal*.

Chipp by his extensive travels in northern and western Africa had thus become one of the recognised authorities on the botany of this extensive region. His last paper, "The Vegetation of Northern Tropical Africa", which is about to be published in the *Scottish Geographical Magazine*, was delivered in the form of lectures given in March last at Edinburgh, Dundee, Aberdeen, and Glasgow. His untimely death is thus not only a great loss to Kew but also to botany. He was indeed a man whose like it will not be easy to find.

A. W. H.

BARON KITASATO, FOR.MEM.R.S.

BY the death of Prof. Kitasato on June 14, Japan has lost its foremost bacteriologist and the medical world one of its most successful workers.

Kitasato made several discoveries of first-rate importance. In 1889 he cultivated, for the first time in a pure state, the bacillus of tetanus, and clearly demonstrated the pathology of the disease, lockjaw, to which it gives rise. In 1890, Kitasato, conjointly with Emil Behring, made the great discovery of antitoxin in the blood of animals immunised against tetanus toxin, and thus laid the basis of serumtherapy. In 1894, Kitasato discovered, isolated, and cultured, for the first time, the bacillus of plague, and in a very exact manner and in an incredibly short time worked out the chief features of this organism so completely as to leave little for his successors to do on the pure bacteriology of plague. Kitasato published many other researches in German and Japanese. In all of his works available to readers of European languages he had always something fresh, and his results, obtained by exact methods, well recorded, have stood the test of time.

Shibasaburo Kitasato was born in December 1852 in the Kumamoto præfecture on the island of Kiushiu. He died in his seventy-ninth year. He studied medicine at Tokyo and graduated there in 1883. He was early a man of promise and (1885) was sent by the Japanese Government to Europe to study bacteriology and epidemiology. He settled at Berlin in the Hygienisches Institut under Robert Koch, then in the zenith of his powers. Kitasato remained six years with Koch. He was a man of exceeding diligence and worked in a room by himself all day and every day. He soon made himself master of the very exact bacteriological technique elaborated by Koch, and he owed a good deal of his subsequent bacteriological successes to his training in Berlin. During the German period of his life, Kitasato published a long series of bacteriological researches. They were almost uniformly good and some were brilliant. Kitasato set himself problems, performed the necessary, often laborious, experiments for their solution, made the correct inferences, and set out his results in model form for others to study and repeat. There was nothing 'woolly' about his work.

On his return to Japan in 1891, he founded a private bacteriological institute in 1892, and a year later it was subsidised by the Government of Japan. From 1899 until 1914 this great bacteriological institute—the Imperial Japanese Institute for Infectious Diseases—was directed by Kitasato with skill and success. Many of his pupils have attained a wide reputation in Europe.

For his valuable services to his country, Prof. Kitasato was chosen a member of the Japanese House of Peers in 1916, and was raised to the peerage with the title of Baron in 1923.

The impression he made was one of great dignity and seriousness, but he talked freely in German on bacteriological subjects. His knowledge of English was negligible.

Kitasato has created for himself by his high-class scientific work an enduring name not only in Japanese medicine but also over the whole world. He was admitted a foreign member of the Royal Society in 1908.

W. B.

WE regret to announce the following deaths :

Lieut.-Col. Sir Charles Bedford, formerly director of the Central Excise Laboratory for India, known for his work on the manufacture and excise control of alcohol in India, on July 8, aged sixty-five years.

Dr. E. G. Echeson, known for his work in electrometallurgy and chemistry, formerly assistant to Edison, on July 6, aged seventy-five years.

Prof. C. H. Kauffman, emeritus professor of botany and emeritus director of the herbarium of the University of Michigan, on June 14, aged sixty-two years.

News and Views.

ON July 25 occurs the centenary of the death of the astronomer, Fearon Fallows, the first director of the observatory founded at the Cape of Good Hope through the action of the Commissioners of Longitude. Born in July 1789, at Cockermouth, Cumberland, the birthplace of Dalton, Fallows was brought up to his father's trade of weaving, but by study and the assistance of a clergyman was able to become a school teacher and then to proceed to Cambridge. Entering St. John's College, he graduated as third Wrangler in 1813, Sir John Herschel being Senior Wrangler, and became mathematical lecturer at Corpus Christi College. On Oct. 20, 1820, he was chosen director of the proposed observatory at the Cape, and to him fell the lot of choosing the site and of installing the first instruments. Immediately on arrival in 1821, with small instruments made by Dollond and Ramsden, he began observations of the principal southern stars, the results of which are contained in his catalogue of 273 stars contributed to the Royal Society in 1824. Later on, he published an account of a series of pendulum experiments. His work was done with but little assistance and in discouraging circumstances. He himself suffered from the effects of sunstroke, and his death at the early age of forty-two years was brought about through scarlatina and dropsy. He died at the naval base, Simons Town, but his grave, marked by a slab of black Robben Island stone, is near the observatory. He left some four thousand observations, which were afterwards reduced by Airy. His successors at the Cape have included Henderson, Maclear, Stone, and Sir David Gill.

ON July 17, in the Public Library of Kingston-on-Thames, a portrait memorial tablet was unveiled to commemorate the work of Eadweard Muybridge, one of the pioneers of modern cinematography. Born at Kingston-on-Thames in 1830, Muybridge emigrated to America, and, joining the staff of the United States Coast and Geodetic Survey, he rose to be director of the photographic surveys. About 1872, a discussion arose among some horse-lovers at the Sacramento racecourse, California, as to whether a horse ever had all four feet off the ground at once. A wager having been made, Muybridge was asked to settle the point with the aid of the camera. Placing on one side of the track a long white screen and on the other twenty-four cameras, he stretched threads across the track which were broken by the horse and released the camera shutters. The results were conclusive and showed that a galloping horse did, at times, have all four feet off the ground. Muybridge's interest was stimulated by this work and he carried on his investigations, publishing a book, "The Horse in Motion", and inventing apparatus for projecting pictures at rates between 12 and 32 pictures a second. In 1880 he invented his zoopraxiscope; in 1881, in Paris, where he met Marey, he also produced moving pictures, and the following year he lectured on the subject at the Royal Institution. He died twenty-seven years ago, bequeathing his zoopraxiscope and lantern slides to Kingston Museum.

AT the ninety-ninth annual meeting of the British Medical Association held at Eastbourne on July 17–25, the president, Dr. W. G. Willoughby, Medical Officer of Health of the town, took as the subject of his address, "Public Health—To-day and To-morrow". Respecting to-day, the situation is not altogether satisfactory, for the Registrar-General's returns for England and Wales demonstrate that there are still far too many deaths at early ages; and that, though the vitality of the nation has steadily improved, the expectation of life is still only fifty-five years for males and fifty-nine years for females. Coincidently with the 40,000 annual deaths of children who escape the risks of infancy, there must be a large amount of sickness among the survivors, causing much indifferent health and permanent physical defects. That this is so is confirmed by the reports of national health insurance and by the wholesale rejections of would-be recruits for the fighting services. In the outlook for the future, owing to the reduction in the birth and death rates, we now have to deal with a population increasingly older than in the past; and as the population becomes older the prospect of a further reduction in the death rate become less, so that if the present course of birth reduction continues, the excess of births over deaths will disappear.

UNFORTUNATELY, as Dr. Willoughby pointed out, there is a greater proportionate reduction in the number of births among the better types of the race than among the less satisfactory, resulting in a mental and physical disadvantage to the race as a whole. The proportion of mental defectives in the population has increased from about four to eight per 1000 in twenty-five years. Birth control is at its minimum among these people, who seem especially fertile. In a minor way, accidents and perilous occupations exact an increasing toll from the nation. There never was a time when so much was expected from the State without individual effort, and lack of such effort and want of employment tend to the acquiring of habits that are not conducive to health. Fortunately, some of the changes that are occurring are favourable to the health of the population, such as improved education. In the later portion of his address, Dr. Willoughby dealt with the relation of the medical profession to the public health, to post-graduate medical study and research, and to the auxiliary medical services.

A COMMUNICATION from Sir Aurel Stein in the *Times* of July 16 gives the first detailed account of the events which led up to the abandonment of his expedition of archæological and geographical exploration in Chinese Turkestan. Every effort had been made to conciliate the Chinese authorities. A memorandum describing the object and scope of the expedition was submitted and fully explained to the Ministry of Foreign Affairs when application was made for a permit; the wish was expressed that a Chinese scholar and topographer should accompany the party, and an undertaking was given that no object of archæological interest would be removed from the country without the previous consent of the Chinese Government. It is obvious that from the very outset a determined effort was made at every possible point to delay the expedition, in order that no work could be undertaken during the coming winter, the only season when archæological exploration is possible in the desert. The party was halted on the frontier of Hsin Chiang while permission to enter the province was obtained, although this had already been granted. This was only the first of a series of difficulties and delays, and in the end it was not until mid-November, some weeks late, that the expedition was allowed to leave Kashgar for Khotan. Even so, Sir Aurel was met at Keriya with the announcement that no digging was permitted, though this had been specifically sanctioned before he left Kashgar. Notwithstanding these obstructions, by the end of April the Tarim basin had been completely circumambulated and much valuable information acquired. At this point the request for a detailed memorandum of the objects of the expedition proved the last straw. As there seemed no prospect of any cessation of vexatious obstruction, Sir Aurel Stein returned to Kashmir.

AN extraordinary meeting of the Institut International d'Anthropologie will be held in Paris on Sept. 20–27 in connexion with the Colonial Exhibition under the honorary presidency of M. Paul Doumer, President of the Republic, and Marshall Lyautey. This special meeting is to be regarded as the fifth Assemblée Générale of the Institut and the fifteenth Congrès International d'Anthropologie et Archéologie prehistorique. The Congress, in accordance with previous practice, will meet in five sections, under presidents as follows: morphological anthropology and study of races (Drs. Vallois and MacAuliffe); human palæontology and archæology (M. le Comte Begouen); eugenics and heredity (Dr. Vignes); psychosociology and criminology (Drs. Papillaut and Paul Boncour); ethnography, folklore, and human geography (M. Louis Marin). Special attention will be directed to topics relating to the French colonies, and in particular to extra-European archæology, a subject which the promoters of the Congress point out is becoming of increasing importance in the archæological field. Reports on problems in this province will be presented from MM. Reygasse, Joleaud, Patte, Laforgue, Benoit, Begouen, Père Koehler and others. Visits to museums, collections, and other places of interest to members of the congress are being arranged. Applications for membership should be addressed to the Secretariat of the Institut International d'Anthropologie, 15 rue de l'Ecole de Médecine, Paris, from which further details may be obtained.

A RECENT communication to the Société Préhistorique Française by Mr. Ludovic MacLellan Mann, in the fourth part of the Society's *Bulletin* for the current year, deals with his discovery of an apparently unique site and a new culture of pre-Chellean age in the gravels of Stanstead, Upper Caterham, Surrey. Systematic excavation in the summer of 1930 brought to light what is claimed to be evidence of human occupation and a flint factory at a depth of 7 metres beneath strata of alluvium, sand, and gravels which are absolutely sterile. Mr. Mann has found material which he regards as a series of implements, finished and unfinished, two hearths, and animal bones. The pressure of the immense mass of superincumbent material and moisture have rendered the flint extremely fragile, and some implements, in addition to artificial fracture, show subsequent natural fracture due to pressure. The number of unfinished implements far exceeds that of the finished, and the small implements are more numerous than the large. The unfinished large implements, which show every stage of manufacture and exhibit what is apparently a new technique, have certain characteristic forms, of which that with a horseshoe cutting-edge is the most typical. The small implements have a wide variation in form, some of them resembling those of the last phase of the stone age. Mr. Mann admits that the implements are difficult to find and identify; nevertheless, he claims that here is unquestionably a workshop site of a new pre-Chellean culture (for which he suggests the name "Stansteadian") of late Pliocene or early Pleistocene date.

THE B.C.G. ('Bacille Calmette-Guérin') vaccine is a culture of a bovine strain of the tubercle bacillus which by cultivation for a number of generations upon a glycerine-bile medium has become non-virulent and is tolerated by bovines. Animals treated with this vaccine become relatively insusceptible to tuberculosis, and vaccination of human beings is now being attempted. Numbers of children have been vaccinated in France, and according to Calmette the incidence of tuberculosis among them is much less than among non-vaccinated children in similar environments. Experiments by Calmette and Wilbert at the Pasteur Institute, French Guinea, upon chimpanzees and monkeys, showed that of vaccinated and control animals kept with infected monkeys, none of the vaccinated and all of the controls became tuberculous. A. Stanley Griffith has carried out a further series of experiments on the protective power of B.C.G. vaccine against tuberculosis in monkeys (Med. Research Council: *Spec. Rep. Series*, No. 152. H.M. Stationery Office, 9*d.* net). His conclusions are that the strain of B.C.G. vaccine used in these experiments can produce local tuberculous lesions in the rhesus monkey, but these are always benign and do not lead to generalisation. Vaccination with it, however, whether by feeding or by injection, has failed to afford the complete protection to monkeys claimed by Wilbert, but may in some instances have produced a low grade of relative immunity. Full details are given of the experiments performed and of the results obtained.

THE ninth International Dairy Congress was held in Copenhagen on July 13–17. The Congress was attended by more than 1600 delegates, of whom 800 came from Denmark, 200 from the other Scandinavian countries, and the remainder from other parts of Europe, the United States, and other parts of the world. About 200 representatives of various agricultural, dairying, manufacturing, and scientific interests attended from Great Britain and Ireland and the Dominions. More than thirty governments sent official representatives. The Congress was officially opened on the afternoon of July 13 by the president, Mr. S. Overgaard, in the presence of His Majesty King Christian X. In the evening the Congress was entertained by the Mayor of Copenhagen in the world-famous Town Hall. The four mornings of the Congress were devoted to sectional discussions of papers covering an extremely wide range of dairying interests: public health legislation and administration, bacteriology, animal husbandry, genetics, biochemistry, dairy machinery, and other interests were all thoroughly represented. The afternoons were devoted to a series of tours to points of interest within a radius of about fifty miles from Copenhagen. These included experimental farms and dairies, bacon factories, typical Danish agricultural units, milk distributing centres, as well as a number of places of less technical interest. A National Dairy Exhibition was also held at the Forum during the Congress week.

HISTORICALLY, perhaps the most important happening at this particular Congress was the formation of a special branch of tropical dairying within the dairy federation. The slow but steady increase of tropical dairying has brought with it its own problems, and congresses like the one just held, even were they to serve no other purpose, would be invaluable in affording opportunities for the discussion of such special problems and for the creation of the machinery necessary to secure the permanent interchange of experience and views about them. The next International Dairy Congress is to be held in 1934 in Berlin, and an invitation was extended by His Excellency Baron G. Acerbo dell' Aterno, the Italian Minister of Agriculture, for the 1937 Congress to take place in Italy.

THE Empire Forestry Association, founded in 1921, has recently issued a small brochure entitled "Forests, an Imperial Treasure", which briefly puts the case of the importance at the present day of the forests of the Empire and their proper development; a personal appeal is also made for more funds, in the shape of additional subscriptions to the membership of the Association. At first sight, the value and the possibilities of propaganda and active assistance to the cause of forestry in all its branches open to such an Association would appear to be of the first magnitude. In some Continental countries the membership of similar associations comprises professional forest officers, private owners of forests, timber merchants, and representatives of many other important industries the raw products of which come from the forest. The trouble in the British Empire has been, and still is, that our people, from cabinet minister downwards, do not possess that instinctive recognition of the value of the forest to the countryside and the benefits, direct and indirect, which the possession of areas of well-managed forests confer upon a country and its people. The brochure of the Empire Forestry Association rightly recognises the enormous potential value of existing Empire forests, a value which, in the opinion of many, has become greatly enhanced as a result of the War. In spite of all substitutes, timber still remains of prime importance. The brochure states, "Timber cannot be immediately produced. . . . It is a question of years—of slow, steady growth, and careful tending from sapling to the forest giant", and the same remains true for the controlling forest staff. It takes time to secure a fully trained and organised forest staff with a graduated service of from 1 to (say) 30 or 35 years. Irregularities in recruiting, cutting down in hard times, and over-recruiting in periods when revenue is abundant, may be a sound policy in the spending departments. But when applied to a forest department, it spells disorganisation both in administration and, more important, out in the forests, where the loss in potential forest revenue is accumulative. The brochure does not make specific mention of this aspect, the foundation of all successful forest management.

THE introduction in 1869 of a number of egg clusters of the gipsy moth into the United States led to no serious consequences until twenty years later. In 1889 the larvæ of this insect caused severe defoliation of trees in the neighbourhood of Boston, Mass., and the rapid spread of the pest into other States led to Congress making an appropriation in 1906 to enable adequate control measures to be taken. The brown-tail moth was first found in 1897 in Somerville, Mass., and its initial spread was more rapid than that of the first-mentioned species. The two kinds of insect demand very similar methods of control, and the whole subject is reviewed by Mr. A. F. Burgess in *Farmer's Bulletin,* No. 1623, issued by the U.S. Department of Agriculture in December. The Federal Government is largely concerned with checking the spread of these insects into uninfested areas, while the affected States themselves aim at reducing the infestations within their own administrative territories. The Government of Canada and several of the Provinces have also organised control and eradication measures within the Dominion. In so far as Canada is concerned, the gipsy moth appears to have been eradicated and the brown-tail moth is found in decreasing numbers. In the United States, the brown-tail moth has also declined very appreciably, and imported parasites have been responsible for a considerable proportion of the good results obtained. Other factors, including spraying operations, have also played their part. With the gipsy moth, imported natural enemies have reduced its numbers in many localities ; but they are not equally effective over the entire infected area, and the best mechanical and chemical methods of control have to be energetically applied. The establishment of a barrier zone, 25-30 miles broad, is an important measure in an attempt to check the westward spread of the insect, and, so far, this appears to have accomplished its purpose.

IN northern Italy the Italian State railways electrified many railway lines with three-phase supply at the low frequency of 16⅔ cycles per second. To increase the output of their converter sets in substations or placed in the open beside the railway, they possess a number of portable substations. These can help any substation that is overloaded or even replace a unit which is temporarily out of commission. The output of a substation must be sufficient for the greatest traffic load even although it occurs very rarely. With portable substations these peaks can be provided for, and so the size of the requisite buildings and machinery for these substations can be reduced. In southern Italy the State railways are now being electrified with 3000 volts direct current. Very favourable results with this system have been obtained on the Benevento-Foggia line, which is being extended to Naples. Further main line railways are being electrified on this system. For example, the railway connecting Bologna and Florence and the railway between Rome and Naples. With direct current obtained from a three-phase supply, the use of portable substations is particularly convenient, as mercury arc rectifiers can be used which occupy little space and are not too heavy. A full description of one of these portable rectifier substations capable of converting 2000 kilowatts, which has been constructed for the Italian State railways, is given in the *Brown Boveri Review* for June. The rectifier is fitted with a high vacuum pump, and so the set can be put into use at once even after a long journey. A photograph is given in the *Review* of a portable rectifier substation, two of which will be in operation this year.

THE generation of water gas by blowing a coke bed alternately with air and steam has an industrial importance which has increased since the process came to be used for preparing hydrogen on a large scale for synthetic and other purposes. This has led to a considerable study of its thermal economy by the Institution of Gas Engineers and by the Fuel Research Board. The preparation of accurate heat balances of a process which consists of a series of rapid alternations of operations at a high temperature presents much difficulty. One method of checking the measurements is to equate, if possible, the heat set free in the 'air blow' with the heat absorbed in the 'steam run', and the results of such a study made at the Fuel Research Station are described in a paper, "The Water Gas Process: a Study of the Carbon and Thermal Balance" (*Technical Paper* No. 30, H.M. Stationery Office, 9*d*. net). Great attention was given to devising methods for metering the gas streams involved and measuring the hitherto indeterminate quantities. In spite of the difficulty of the task, it was possible to account as heat absorbed on the 'run' for 90 per cent of the heat evolved in the 'blow'. The remainder unmeasured is equivalent to about 3·3 per cent of the coke fed into the generator. It is of the same order as estimated losses during clinkering and by radiation.

WE have received the first number of a new publication, "Occasional Notes of the Hong Kong Horticultural Society" (No. 1, February 1931), edited by Dr. G. A. C. Herklots. In a foreword, the editor points out that within the small territories of Hong Kong very diverse conditions prevail, from the point of view of the gardener, from Victoria Peak with its winter fogs and cool nights to the warmer conditions of the lower levels and Kowloon. It is proposed in the new journal to deal with the special problems relating to the cultivation of particular plants in Hong Kong (sweet peas are dealt with in this number) and also to describe various genera of interesting plants, species of which have been introduced to Hong Kong gardens, and five species of *Thunbergia* are thus dealt with and illustrated in four simple line drawings. Mr. R. A. Nicholson contributes notes on the cultivation of various garden favourites, roses, carnations, dahlias, etc., under Hong Kong conditions; whilst the editor contributes a note upon the soils of the Hong Kong territories. These soils, formed by the weathering of igneous rocks under tropical conditions with relatively heavy rainfall, tend to be of the red laterite type, poor in the necessary salts and becoming acid in reaction. This note is useful as pointing the way both to empirical manurial treatment and also to a more thorough scientific study of the soils of the territories when the workers are available. If this new journal can fulfil the task it has set itself, it should prove a very useful medium for spreading information and stimulating inquiry and research upon horticultural problems both in Hong Kong and in a wider field.

THE annual report of the Smithsonian Institution upon its "Explorations and Field-work" for 1930 reveals again that energy and lavish expenditure which are the envy of other countries. Field expeditions, not content with concerning themselves with twenty-three of the States of their own country, touched upon every continent and upon many islands. The subjects of the expeditions were as different as their objectives; they included the radiation of the sun, the ancient Eskimo culture of Alaska, Indian music, the fauna and flora of central China, birds of Spain, fossil horses in Idaho, and so on. It might be said that the scientific value of the expeditions varied also. That to Spain, for example, must have partaken rather of a collecting excursion for the replenishing of cabinets, for European zoologists have already done pretty well by the birds of Spain; one feels, indeed, that such a theme might well be left to them, and that energies should rather be concentrated on work lying to hand likely to yield fresher results. Many of the expeditions, however, were of fundamental importance; we need only cite Dr. J. W. Gidley's collecting in the fossil bone deposit at Hagerman, Idaho, which seems to have been a watering place for the wild creatures of the region, so many hundreds of skeletons remain there. Sufficient material of the rare extinct horse, *Plesippus*, was collected to build three or four complete skeletons.

WHILE progress has been made in Great Britain in the study of oil-paintings by microscopic analysis, largely through the work of Prof. A. P. Laurie, experts on the Continent have also been turning their attention, with great effect, to this recent and fascinating branch of research. The variety of aims and methods employed is so considerable that an International Conference, organised by l'Office International des Musées, was held on Oct. 13-17, 1930, in Rome, "for the study of scientific methods applied to the examination and preservation of works of art". With commendable promptitude the papers read at the Conference have been published in the journal of the International Office of Museums, *Museion* (vols. 13-14, 1931). Subjects of discussion included the optical examination of paintings, the chemical and micro-chemical analysis of paintings and mural decorations, the importance of the use of X-rays and its limitations; and an introductory paper by J.-F. Cellerier deals generally with scientific methods and usages in the examination of paintings. Otherwise the magazine contains much information of interest to curators of art collections. There is a short summary in English of the chief papers.

"POSITIVE Eugenics in Practice" is the title of an article in the April issue of the *Eugenics Review* (vol. 23, No. 1). The writer, Mr. Alfred Dachert, conceived the idea many years ago of founding a township for the express purpose of housing couples who would be likely to raise healthy families. In 1921 the city of Strasbourg, realising the significance of the work, placed a site at his disposal, and with funds contributed by the company he managed, building was commenced and 140 houses are now completed, specially planned so as to avoid unnecessary labour for the young housewife. As tenants for the purpose in view, it was necessary to find healthy, vigorous, and comely young couples who really wanted children, and a system of selection was adopted, based upon the application, an interview, visitation of the present home, and medical examination. The experiment seems to be an unqualified success, the birthrate is much higher than in the city of Strasbourg itself, and the behaviour of the citizens has been exemplary. To maintain its purpose, infertile couples have to be replaced by others, but this has been necessary only in nine instances during the seven years since the birth of the township.

VITAMIN A has been shown by Green and Mellanby to be of value as an anti-infective agent when given in large doses. The British Drug Houses, Ltd., London, N.1, have recently put on the market a preparation made from mammalian liver under the name of Avoleum, which, unlike their original product, Radiostoleum, contains no added vitamin D. As mammals, unlike fish, do not store the latter in their livers, the concentrate may be considered to be free from the anti-rachitic factor. The blue value by the antimony trichloride test is about ninety times higher than that given by an average good codliver oil. The concentrate is also standardised in rats by its power of promoting growth and preventing and curing xerophthalmia in comparison with a known sample of codliver oil. Avoleum is suitable for administration in acute conditions in which massive doses of vitamin A are required and also in cases in which vitamin D is contra-indicated. It is issued in capsules, each containing 3 minims of the solution: the dose is 1–3 capsules daily.

IT is announced in *Science* that the Roosevelt Memorial Association, New York, has awarded a Roosevelt Medal to Dr. C. Hart Merriam, chief of the U.S. Biological Survey from 1885 to 1910, and since then research associate of the Smithsonian Institution.

THE following have been elected to fill the vacancies which will occur in the Council of the Institution of Electrical Engineers on Sept. 30: *President*, Capt. J. M. Donaldson; *Vice-Presidents*, Mr. J. M. Kennedy and Mr. F. W. Purse; *Hon. Treasurer*, Mr. E. Leete; *Ordinary Members*, Lieut.-Col. A. G. Lee, Mr. C. le Maistre, Mr. H. A. Ratcliff, Dr. E. H. Rayner, Mr. R. H. Schofield, Mr. J. W. J. Townley, and the Viscount Falmouth.

THE International Congress of Mathematics will be held at Zurich on Sept. 4–12, 1932. There will be general discussions on the present position of mathematics, also short papers of recent research work. In connexion with the Congress, receptions and excursions are being arranged. Further details will be available in October.

REFERRING to a paragraph that appeared in NATURE for July 4 (vol. 128, p. 15), the Rev. J. P. Rowland, *S.J.*, informs us that, with the aid of addiditional records (the total number used being twenty), he has made a new determination of the position of the epicentre of the North Sea earthquake of June 7. This he finds to be in lat. 53° 57′ N., long. 1° 25′ E., or about 22 miles to the north-east of the position previously assigned, the corresponding time at the origin being 0 h. 25 m. 24 s. G.M.T.

THE London Natural History Society has recently published a pamphlet describing its constitution and activities. Founded in 1858, its present headquarters are at the London School of Hygiene and Tropical Medicine. The president is the Right Hon. Viscount Grey of Fallodon. Members of the Society enjoy the privileges of admission to all lectures, use of the Society's collection and library, receipt of the annual copy of the *London Naturalist*, and access to places of interest. The Society is divided into archæological, botanical, entomological, ornithological, plant galls, and rambling sections. The annual subscription is 7*s.* 6*d.*, with an entrance fee of 2*s.* 6*d.* Application for membership should be made to the Secretary, 91 Queen's Road, Buckhurst Hill, Essex.

THE Empire Marketing Board has made a grant of £15,790, spread over five years, towards a scheme for the development of rice research in India which aims at increasing the yield and improving the quality of Indian rice. The scheme is organised by the Imperial Council of Agricultural Research of the Government of India. The Empire Marketing Board has offered to bear half the cost of developments in Burma, the principal rice-exporting Province, and Bengal, where Patna rice is grown for export. Schemes for development of research in the remaining five Provinces are to be financed entirely by the Imperial Council. About 33,000,000 tons of rice are produced annually in India, of which only a small proportion is exported. The scope for research is immense. Improvement may come through breeding better varieties of rice already grown in India, or through establishing there new and better kinds of rice from other countries. A beginning has already been made and more than a million acres are under improved varieties.

THE Ministry of Health has published a "Review of certain Present Aspects of Smallpox Prevention", which deals with the subject particularly in relation to the vaccination acts (*Reps. on Pub. Health and Med. Subjects*, No. 62. H.M. Stationery Office. 1*s.* net). It is concluded that in spite of the fact that England and Wales, of the population of which some forty per cent are unvaccinated, are intrinsically more vulnerable to the serious and rapid spread of severe epidemic smallpox than are countries where the population is compulsorily vaccinated and re-vaccinated, the protective methods which are part of ordinary British administration should prove efficacious in protecting the community from invasion. Post-vaccinal encephalitis is also discussed, and the vaccination requirements of certain European countries are summarised.

THE *Annual Report* of the Calcutta School of Tropical Medicine, Institute of Hygiene, and the Carmichael Hospital for Tropical Diseases, 1930, recently issued (Calcutta: Bengal Government Press, 1931), contains summaries of the work, routine and research, carried out in the laboratories and wards. Lieut.-Col. Acton, the director, in his introduction, after alluding to some of the administrative difficulties of the post, gives a useful review of the recent advances in tropical medicine. Recent investigations indicate that epidemic dropsy, vast epidemics of which have occurred in Calcutta from time to time, is connected with the consumption of badly stored rice, and is related to beriberi. Promising results have been obtained in the treatment of oriental sore with local injections of a 2 per cent solution of acid berberine sulphate. The growth of the *Leishmania* parasite of this disease in culture is completely inhibited by a dilution of 1 : 80,000 of this drug.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant master for science and engineering at the Oswestry Technical Institute—The Clerk to the Governors, Technical Institute, 18 Arthur Street, Oswestry (July 26). A lecturer in civil engineering in the Faculty of Engineering of the University of Bristol—The Secretary and Acting Registrar, University, Bristol (July 27). A temporary investigator under the Department of Agriculture for Scotland, in connexion with an investigation of the marketing of grain and grass seeds in Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (July 29). A lecturer in biochemistry (fermentation industries), at the Heriot-Watt College, Edinburgh—The Secretary, Heriot-Watt College, Edinburgh (July 31). A part-time assistant in the Department of History and Method of Science of University College, London—The Secretary, University College, Gower Street, W.C.1 (Aug. 4). A veterinary education officer under the Derbyshire Education Committee—The Director of Education, County Education Office, St. Mary's Gate, Derby (Aug. 5). A head of the Building Department of Woolwich Polytechnic —The Principal, Woolwich Polytechnic, S.E.18. A master for manual instruction, principally in woodwork, under the Middlesex Education Committee—The Secretary, Education Offices (H), 10 Great George Street, S.W.1. A teacher of carpentry and joinery at the Tottenham Polytechnic—The Principal, Tottenham Polytechnic, High Road, N.15. Constitution of Lithium.

THE first measurements of the relative abundance of the isotopes 6 and 7 of lithium were made by Dempster with his magnetic spectrograph.[1] As the instrument indicated ratios so high as 37 and so low as 4·8 with means around 7–10, the results are of little value. Morand,[2] using a heated anode and measuring simultaneously the currents carried by Li^6 and Li^7, arrived at the figure 14·9, a ratio agreeing well with the atomic weight 6·94 on the assumption that the atoms had exact whole number masses. Costa's measurements (1925) recalculated from my own results[3] indicate the masses to be 6·012 and 7·012 ($O^{16} = 16$) respectively. This reduces the ratio calculated from the chemical atomic weight to about 13. Quite lately, v. Wijk and v. Koeveringe,[4] from observations on band spectra, calculate the ratio to be 7·2.

Recent improvements in technique have enabled me to apply the principle of accelerated anode rays to my high resolution mass-spectrograph. Using the method of intermittent exposures and correcting for the position of the lines, I find a provisional value of the ratio to be 10·2 ± 0·5, which gives:

$$\text{Atomic weight of Li} \geqq 6{\cdot}923 \pm 0{\cdot}006.$$

The correction for position is unfortunately a maximum, about 20 per cent, for the lithium lines. In addition, it must be noted that the velocity of the Li^6 atom exceeds that of the Li^7 atom by about 8 per cent, and will certainly enhance its photographic effect. Any correction for this will increase the ratio, and although it seems unlikely that it could bring it up to the high value given by Morand, it can only accentuate the very serious discordance between the ratio calculated from band spectra and the more direct results of the mass-spectrograph. It seems highly desirable that measurements similar to those of Morand should be made with an instrument of higher resolving power; the magnetic spectrograph of Bainbridge would seem to be admirably suited to the purpose.

Polarisation of a Beam of Electrons by Scattering.

MOTT[1] has predicted that a polarisation of an electron beam is possible under certain conditions. These conditions are that a fast electron shall be scattered successively by two heavy nuclei through large angles. The intensity of the twice-scattered beam should then depend on its azimuth with respect to the original unscattered beam. Many attempts have been made to detect such an effect, with either negative or inconclusive results; but in none of them have the conditions laid down by Mott all been fulfilled. Chase,[2] who finds a small positive result, scattered β-rays through 90° from solid targets. The scattering in a solid target is multiple, that is, consists of a large number of small angle collisions, and Mott's theory is completely inapplicable. The same criticism applies to the work of Langstroth,[3] who, moreover, uses too small a velocity (due to an error in Mott's paper) for the polarisation to be detectable. In the recent work of Rupp[4] and Rupp and Szilard the arrangement is still further removed from that considered by Mott.

When the conditions of nuclear scattering are satisfied, it appears from the work described below that there is a small polarisation of the beam, in the direction predicted by the theory. Electrons of velocities up to 70 kilovolts (0·47 of the velocity of light) are scattered through 90° by a target of the thinnest commercial gold leaf (thickness $< 10^{-5}$ cm.). The scattered beam, defined by suitable diaphragms, meets an exactly similar target, and is scattered again through 90° to a Faraday cylinder, where it may be measured. The second target and Faraday cylinder can rotate about an axis joining the two targets. A thin aluminium foil (thickness 8×10^{-5} cm.) placed between the second target and collecting cylinder, holds back all slower secondary electrons, but allows the greater part of the scattered beam to pass. Precautions were taken to exclude all electrons coming from other parts of the apparatus than the two targets, and also all photoelectrons produced by X-rays.

The difference in intensity of the scattered beam in the two positions, parallel and antiparallel to the original beam, proved very small and of the same order of magnitude as the natural asymmetry introduced by the apparatus itself. In order to eliminate the latter, the difference in the polarisation produced at 70 kv. and at 20 kv. has been observed. The results are given in the accompanying table, where the differences in the intensities of the two scattered beams are shown as percentages of the antiparallel beam. The table represents some 140 determinations at each velocity; each group represents a taking down and reassembly of the apparatus to replace the filament or one of the foils. One group is omitted which gave a result, discordant with all the others, of 9 per cent.

Group.	Difference in Polarisation 70 kv.-20 kv. (per cent).
A	1·60 ± 0·77
B	2·48 ± 0·75
C	3·66 ± 1·12
E	0·59 ± 0·62
F	3·93 ± 0·65
G	1·36 ± 0·37
	0·65 ± 0·48
H	1·57 ± 0·58
J	3·80 ± 1·24
O	2·09 ± 0·42
Weighted mean	1·74 ± 0·32

The theory of Mott indicates that the amount of polarisation should depend on the square of the atomic number of the scattering nuclei. In order to check whether the very small effect found is not entirely instrumental, one of the gold foils was replaced by aluminium (thickness 8×10^{-5} cm.). The total scattered intensity was too small to allow both scatterers to be of aluminium. The result found (for the difference at 70 kv. and 20 kv. again) is 0·01 ± 0·23 per cent, justifying the view that a real polarisation effect has been observed.

The work of Mott indicates a value of 0·4 per cent (with an arithmetic mistake on p. 439 of his paper corrected) for gold, as the difference in the polarisations at the two velocities used; this is one quarter of that actually found, but I am assured by Mr. Mott that for an atomic number so high as 79 his series cease to converge and the final formula loses all validity. The problem requires working out to a higher approximation before the results can be applied to scattering by the heavier nuclei.

It should be mentioned that the experimental result of 1·74 per cent is more likely to be low than high. The foils used were highly inhomogeneous, and multiple scattering, which is not expected to contribute to the polarisation, from the thicker parts is certainly present, but to an unknown degree.

It is hoped to publish a fuller account of the experiments in the near future.

A Curious Phenomenon shown by Highly Charged Aerosols.

IN the course of investigations on the electrification of aerosols, a curious phenomenon was noticed. The aerosols were volatilised in a glass chamber of about four cubic metres capacity. During the dispersal a unipolar discharge was produced by connecting one pole of a large electrostatic machine to a metal brush inside the chamber. The contents of the chamber were agitated by an electric fan during dispersal and for a minute or so afterwards.

Whenever this type of aerosol is produced in our chamber, a striking phenomenon makes its appearance. Directly the fan has stopped, large particles begin to arrive in the centre of the chamber, and these gradually draw together to form a large, loose, more or less spherical cluster about 20 centimetres in diameter, the particles, however, retaining their individuality. The particles composing the sphere appear to be highly electrified, since, if a charged wire is pushed towards it, the sphere as a whole is rapidly attracted and absorbed when the wire is of one sign and repelled by the other. In this way the sphere may be pushed right across the chamber, though it may be distorted in the process. If now the wire is removed, the sphere tends to return again to the centre.

The greater number of particles when examined by the electric cell, which we have previously described,[1] are seen to be very highly charged to the same sign as the brush discharge. The particles composing the sphere, on the other hand, are highly charged to the opposite sign. Thus if the aerosol is charged positively by a positive brush discharge, the sphere is made up of negatively charged particles and vice versa. The phenomenon is exhibited by all aerosols which we have examined, but is especially striking in the case of a dyestuff such as *p*-xylene-azo-*β*-naphthol. An aerosol of this material when dispersed at a concentration of about 15 mgm. per cubic metre is greenish blue in a Tyndall beam, and after electrification retains this colour. The sphere which forms in the centre of the chamber, however, is bright red, this being the colour of large particles of the material.

By inserting a cover-glass into the cluster, it was found possible to collect some of the particles, and microscopic examination showed that they consisted of long chains or ropes of particles containing apparently thousands of units.

The phenomenon may probably be explained as follows. Suppose we consider an aerosol which has been positively charged by a positive brush discharge. The outside of the glass walls of the chamber immediately after dispersal is found to be highly positively charged. This implies that the inside is negatively charged by induction, though we have not been able to verify this experimentally. If then complexes carrying a high negative charge are present in the chamber, they will certainly be repelled towards the centre. On reaching the centre, their mutual repulsion will prevent very close approach, so that a loose sphere should be formed.

The complexes themselves may be formed in the following way. Whilst, for example, the positive brush discharge is in action, heavy negative charges must be induced on any objects near the brush. Now experimentally we find that if there are two point electrodes with a field of a few hundred volts per cm. between them in an aerosol, long chains of particles will gradually form and project out from the points. These chains may easily be detached by an air current, and will presumably remain as long chains, providing that the cohesive force between the particles is greater than the repulsive force due to their charge. A similar state of affairs will probably obtain whilst the brush discharge is in action. When the fanning ceases, the negatively charged chains will obviously be repelled to the centre of the chamber, whilst those positively charged will be attracted to the walls.

It may be noted that if the sphere is once completely removed in any way, it will not reform, and that in any case it tends to disperse with lapse of time. This latter may be attributed partly to gradual neutralisation of the charges on the complexes by coagulation with particles of opposite sign and partly to loss by leak of the charge induced on the glass walls.

The existence of such a spherical, highly charged assemblage of particles suggests that globular lightning may owe its origin to an analogous effect, in which particulate matter, either liquid or solid, is charged to a very much higher potential.

Temperature Stability and Denaturation of Serum Albumin.

IT has been shown by Svedberg and Sjogren[1] that at ordinary temperature serum albumin is stable (that is, homogeneous with regard to molecular weight) in a region of pH varying between 4 and 9. These authors have also shown that outside of the stability region, but not too far from it, the serum albumin molecule is dissociated into smaller molecules. This first stage of breaking up of the molecule probably means the formation of particles of half the weight of the original molecule. The complete breaking up of the molecule follows immediately after this stage. The first stage has been shown to be reversible with regard to the molecular weight.

Now the influence of different heat treatment on serum albumin in different buffered solutions has been studied by means of the ultracentrifugal technique worked out by Svedberg and the electrophoretic technique worked out by Tiselius,[2] and it was found that there is a distinct difference in the behaviour of the serum albumin inside and outside the stability region. Inside the stability region, different proportions of the total quantity of the serum albumin will undergo change and give aggregation products, the number and size of these aggregation products varying according to the pH and to the salts of the solution, to the temperature and the time during which the heat treatment has taken place. That part of the serum albumin which has undergone aggregation may, if not already coagulated, be removed by centrifuging, and it is then found that the serum albumin in the remaining solution is quite unchanged. It was found to have exactly the same sedimentation constant, the same molecular weight, the same electrophoretic movement, and the same light absorption as the original solution. This may be a property peculiar to serum albumin.

Some preliminary experiments with amandin have shown that this protein undergoes quite a different change by heat treatment. In this case the protein is partially split up into very small particles, so small that they do not show any sedimentation in the ultracentrifuge. But, as in the case of serum albumin, the main part of the amandin is found to be unchanged in the solution, if the treatment has not been too strong.

The aggregation products can be centrifuged off and washed, and they can be suspended in a buffer solution. Such suspensions have been examined by electrophoresis, and they were found to be homogeneous with regard to electrophoretic movement, in spite of being quite polydisperse in the ultracentrifuge. The *p*H mobility curve of this denatured serum albumin was found to be nearly parallel to that of the native serum albumin, but the isoelectric point was found to lie between *p*H 5·1 and *p*H 5·3 instead of at *p*H 4·88 for the native serum albumin in the same buffer solutions. This seems to indicate that the native serum albumin has undergone a definite chemical change when transformed into the denatured serum albumin.

The acid limit of the stability region was found at about *p*H 3·8. At this point the solution was treated for six minutes in boiling water, and yet the sedimentation constant was unchanged and there were no aggregation products, but the diffusion constant showed a drift indicating that the particles were not quite monodisperse.

Outside the stability region, at *p*H less than 3·8, it was found that the serum albumin particles were split up into smaller particles giving a sedimentation constant of about $s_{20} = 3{\cdot}5 \times 10^{-13}$ instead of $s_{20} = 4{\cdot}3 \times 10^{-13}$ for native isoelectric serum albumin, and this was the case even if the solution had been treated in boiling water for five to ten minutes. Inside the stability region in buffers containing the same ions this treatment would always cause coagulation or the solution would at least be opalescent, indicating the formation of aggregation products.

By electrophoretic experiments it was found that the heat-treated solutions (at *p*H less than 3·8) gave such mobilities as would be expected for denatured serum albumin at these hydrogen ion concentrations. After standing one day at room temperature, an untreated solution of serum albumin (at *p*H less than 3·8) showed the same mobility as the one treated by heat.

When the hydrogen ion concentration of a heat-treated solution (at *p*H less than 3·8) was changed to about the isoelectric point, it was in some cases found that such a solution in the ultracentrifuge was not distinguishable from a solution of native serum albumin, but in some other cases there was found a sedimentation constant of about $s_{20} = 3{\cdot}6 \times 10^{-13}$; but in these cases the electrophoretic mobilities were not those of native serum albumin but those of denatured serum albumin.

Some preliminary experiments have shown that serum albumin solutions at *p*H 3·5 exposed to ultraviolet light are strongly changed, and it is found that the light absorption increases very much, the odour becomes very peculiar and strong, the solution remains clear, but the sedimentation constant is about twice that of native serum albumin, and the diffusion constant shows a strong drift.

Experiments to reverse the coagulation either with potassium thiocyanate or acetic acid were negative; the results were inhomogeneous polydisperse solutions. An experiment with heat treatment at *p*H about 10 showed that the serum albumin was split up and gave a sedimentation constant of $s_{20} = 3\ 5 \times 10^{-13}$, but the diffusion constant showed a strong drift, and the light absorption was about five times as large as usual, which indicates that a deeper chemical change had taken place.

A New Relation between Electrical Resistance and Energy of Magnetisation.

IN two recent papers[1] I have shown that there are two effects of a magnetic field on the electrical resistance of ferromagnetic wires. At temperatures appreciably below the Curie-point (*C-P.*) there is an increase $+\Delta R$ of the resistance by magnetisation which attains a saturation value exactly at the saturation of the magnetisation. The relation between the magnetisation I and the change of the resistance is $+\Delta R = c(I^2 - I^2_0)$, where I_0 is a critical value of the magnetisation process; for example, in crystals the component of the spontaneous magnetisation in the direction of the field. So far as the limit I_0 of the magnetisation, there is practically no change of resistance. The greater part of the resistance increase takes place in the region approaching saturation.

At temperatures in the neighbourhood of the *C-P.* the magnetic field decreases the resistance. Just below the *C-P.* there is at first a small increase and then a decrease of the resistance; above the *C-P.* we find only a diminution of the resistance. We have put forward the hypothesis that in a ferromagnetic material the spontaneous magnetisation produces a diminution of the resistance, and have shown that in the absence of an external field this effect is exactly proportional to the inner magnetic energy: that is, to the square of the spontaneous magnetisation. Since in the neighbourhood of the *C-P.* an external magnetic field gives an augmentation of the magnetic energy (proportional to the square of the 'true' magnetisation), the resistance should be diminished by a field, as is observed. There, however, a difficulty appeared; for we found that between 0 and 500 gauss $-\Delta R$ is approximately proportional to the first power of the field. In a letter to NATURE,[2] H. H. Potter has confirmed our results, and has also shown that, in fields high enough and at temperatures above the *C-P.*, the decrease of resistance is proportional to the square of the field, as would be expected from our theory.

In continuation of our experiments, we have measured again as exactly as possible the diminution of the resistance and also the magnetisation at temperatures above the *C-P.* at low field-strength. We have found that the decrease of resistance is always proportional to the square of the true magnetisation $-\Delta R = c.\sigma^2$ and is independent of the relation between R and H. Just above the *C-P.* the external field has a double influence on the magnetisation: it produces a true magnetisation and also a certain form of ferromagnetic magnetisation. The fact that there the two effects will be superposed, explains our observation that the negative change of resistance can be approximately proportional to the first power of the field.

We would suggest that these experiments, in connexion with the results of Potter, *show definitely that true magnetisation diminishes the electrical resistance proportionately to the true magnetic energy.*

Wires drawn through Rotating Dies.

A chance observation by one of us (H. G.) that if the die through which a wire was being drawn was simultaneously rotated the tension required was appreciably reduced, has led to results of considerable interest. The following series of values refer to an 80:20 cupro-nickel wire reduced from 0·073 in. to 0·0635 in. in diameter, that is, 24 per cent. A sintered tungsten carbide die of 6° taper was used, with 'Oil-dag', a suspension of colloidal graphite in oil, as a lubricant.

Speed of Rotation. r.p.m.	Tension required lb.	Decrease. Per cent.	Power to rotate Die. ft.lb./min.
0	82	0	..
50	61	26	200
80	58	29	450
160	51	38	700
1920	26	68	1000
2660	23	72	1300
3300	21	75	1400

Since the speed at which the wire was drawn in these tests was only 3 in. per min., it will be appreciated from the values given in the last column that the observations are at the moment of theoretical interest only, and have no industrial significance. Whether this still holds at higher rates of drawing we have not yet determined, but work in this direction will be undertaken.

Up to the present we have been unable to detect with certainty any change in the structure of the wire drawn through fixed and rotating dies, nor have we found any alteration in the recrystallisation on annealing. The very few mechanical tests so far carried out reveal no modification in the tensile properties of the wire, though the number of twists withstood—on a length of 100 times the diameter of the wire—appears to be less with the rotating die than for wire drawn through a stationary one. Typical results, which refer to a 70 : 30 brass wire again reduced 24 per cent from an initial diameter of 0·073 in., are given below.

Die.	Maximum Stress, Tons/sq. in.	Elongation Per cent on 2 in.	Reduction of Area. Per cent	Torsions.			
				1	2	3	Mean.
Fixed	34·5	25	55	115	106	111	111
Rotating	34·3	25	55	87	65	72	75

The Brinell hardnesses of the wires were again almost identical. Using a 1 mm. ball and a load of 30 kgm. the Brinell number was 125 for the fixed die and 123 for the rotating one.

Diamagnetism of Liquid Mixtures.

Mr. S. P. Ranganadham states, in Nature of June 27, that he has obtained values for the specific susceptibility of mixtures of organic liquids which differ markedly from those obtained by us.[1] It is impossible to answer Mr. Ranganadham's assertion without a full knowledge of his data, consequently we must await the publication of his results before we can reach an opinion as to the comparative value and accuracy of the two sets of values. In the meantime, however, we must justify our continued belief in the accuracy of our work. In the first place, as pointed out in our paper, the specific susceptibilities of the pure liquids used in our experiments were found, with a single exception, to be closer to Pascal's calculated values than any values hitherto published. We attribute this fact to the carefully checked purity of the material used. The susceptibility values used in plotting our curves were, in every case, obtained several times with fresh portions of the mixtures; the symmetry of the curves and the fact that they exhibit maxima in the same positions as other property-composition curves is confirmatory of the accuracy of our results.

It is well known that acetone-chloroform mixtures show greater deviations from the mixture law than almost any other pair of organic liquids; it would, therefore, not appear to be extraordinary that the specific susceptibility should also show a very marked deviation such as we find. Furthermore, as pointed out in our paper, we found it possible to calculate a mass action constant for the reaction between the constituent liquids and an equimolecular compound from the specific-susceptibility-composition curve for acetone and chloroform.

Mr. Ranganadham sees with astonishment that this curve passes from the diamagnetic to the paramagnetic region. Whilst this fact is remarkable, it is of experimental origin and, in our opinion, not open to doubt. In our view, the astonishing fact is that although we have no evidence that acetone and chloroform combine under our conditions to give dimethyltrichloromethyl carbinol, this substance, originally made by Willgerodt, is considerably more paramagnetic ($\chi = +2{\cdot}564 \times 10^{-6}$) than any of our mixtures of acetone and chloroform. Further work on the physical properties of acetone-trichloroethylene and bromoform-acetone mixtures is about to be published, and this fully supports our published curves for the specific susceptibility of mixtures of these substances.

Excretion of Uric Acid.

Dr. Wigglesworth's communication in Nature of July 18 raises some very interesting points regarding the physiology of animals which possess uricotelic metabolism. Evidence in favour of his suggestion that a circulation of base takes place, as well as of water, in the excretion of uric acid, can, it seems to me, be found in the facts already known about the development of the chick embryo.

The use of the term 'urates' for the solid masses present in the allantoic liquid during the last week of incubation rests on nothing more than an assumption. For (1) the inorganic cations of the allantoic liquid are completely accounted for by the inorganic anions, as is shown by the recent work of Iseki.[1] Moreover, (2) the concentration of ash on the fourteenth day of development in the allantoic liquid is almost exactly the same as it was on the ninth, although a 550 per cent increase in the concentration of uric acid has taken place. (3) The uric acid cannot be combined as ammonium urate, for there is not enough ammonia present in the allantoic liquid. About ten times as much as what is found there[2] would be required to form ammonium urate. (4) The slimy masses of uric acid in the allantoic liquid towards the end of development, when washed in distilled water and ashed, give an ash content of only 3·9 per cent. Sodium urate would require 12 per cent and potassium urate 18 per cent. (5) The *p*H of the allantoic liquid, which is about 6·3 during the last week of incubation[3] also strongly suggests that the uric acid is not present as urate.

It seems justifiable, then, to conclude that the uric acid which accumulates in the developing chick's allantoic cavity is free. It may enter the allantois in the form of the sodium or potassium salt, and the cation may then be reabsorbed as carbonate or in some other way, but such an absorption of base might presumably take place just as well in the developing kidneys or cloaca. However, it is known that the allantoic blood-vessels absorb water from the allantoic liquid after the tenth day, and, as they certainly take part in a circulation of water, they may take part in a circulation of base as well.

The Slow Combustion of Acetylene.

IN a recent paper, Bodenstein[1] has propounded a theory of the slow oxidation of acetylene, which accounts extremely well for the observed[2] kinetic phenomena. However, he considers the chain length to be of the order of one link, contrary to the generally accepted mechanism of hydrocarbon oxidation. That acetylene and oxygen form a reaction chain of considerable length is evident from the following experiments, carried out at 320° C. in a circulating apparatus of the same design as that described by Spence and Kistiakowsky.[2] Using an unpacked pyrex glass furnace of 75 c.c. volume, with an internal diameter of 20 mm., and circulating a mixture of 276·6 mm. of acetylene and 147·2 mm. of oxygen, 51·4 mm. of acetylene reacted in one hour. When, however, a furnace packed with pyrex glass tubing of 2 mm. internal diameter and having a total free gas volume of 75 c.c. was substituted for the unpacked vessel, using the same initial amounts of acetylene and oxygen, less than 1 mm. of acetylene had reacted after one hour. Also, a much slower reaction was observed when the surface of the unpacked vessel was coated with potassium chloride.

There can be no doubt, then, that under the conditions stated the amount of reaction taking place upon the glass surface itself is insignificantly small, while it seems most probable that reaction chains originate upon the surface, undergo considerable branching in the gas phase, where some deactivation by oxygen occurs, and finally are broken at the walls of the vessel. Chain reactions of this type have been discussed by Semenoff[3] (see also Bursian and Sorokin[4]), who shows that they are accompanied by an induction period the duration of which depends upon the concentration of active centres, that is, upon the nature of the surface, upon the total probability of forming another link, and upon the time necessary for the propagation of each link in the chain. A more detailed account of other experiments bearing on this point will be published shortly.

Diamagnetism and the Colloidal State.

SOME preliminary experiments by Vaidyanathan[1] show that the diamagnetic susceptibility (χ) decreases as the size of the particle is reduced in the cases of the colloids of bismuth, antimony, and graphite. Detailed and careful experiments by me with much stronger fields have in general confirmed this result. The quantitative variation of χ with the diameter d of the particle has also been studied. The results for bismuth and antimony are affected by oxidation, but in the case of graphite there is no such trouble. A graph drawn between χ and $1/d$ for this element gives a straight line. The inverse of the diameter is a measure of the surface or boundary area of a number of spherical particles in unit mass of the substance. It is thus found that χ decreases proportionately as the boundary area of a given mass is increased.

The results for bismuth and antimony are equally interesting. The curves between χ and $1/d$ are such as could be explained on the basis that the decrease of χ is due to two causes, namely, oxidation and the genuine fall on account of the reduced particle size.

It is interesting to note that as the boundary area is increased the orbits of a large number of *structure electrons* postulated by Prof. O. W. Richardson[2] will decrease in size. This, on the orbital theory, may account for the decrease in the diamagnetic susceptibility value as d is reduced. The fact that χ decreases proportionately as the boundary area is increased seems to lend considerable weight to this view.

The late Mr. Herbert Tomlinson, F.R.S.

THE obituary notice of Mr. Herbert Tomlinson in NATURE of July 11, p. 58, reminds me that, about a year ago, I came across what appears to be a complete collection of his published work for sale in a second-hand bookseller's shop in Worthing.

This collection consists of three thick octavo volumes which were evidently bound for his private use, as the pamphlets and articles are interlined with letters to and from the secretary of the Royal Society, the Editor of NATURE, etc., and there is an index in his own handwriting.

It contains, in addition to his formal scientific papers, many cuttings of letters to the *Times*, and articles which were printed in chemical journals and in North London papers. There are also quite a considerable number of literary articles, mainly on the subject of Italian poetry ; and several metrical versions of Dante and Tasso which indicate that the author was no mean poet.

The volumes are now in the library of King's College, Strand, W.C.2, where they are available for reference by anyone interested.

J. JOHNSTON ABRAHAM.

38 Harley Street, W.1.

Research Items.

Pit-Dwellings at Kiatuthlanna, Eastern Arizona.—Ruins on the Long H ranch, Twin Salt Lakes, in Apache County, were excavated by Mr. Frank H., H. Roberts, jr., on behalf of the Bureau of American Ethnology in 1929, the results being described in *Bulletin* 100 of the Bureau. By the end of the field season, eighteen pit-houses, the remains of jacal structures, and a pueblo ruin with forty-nine rooms and four kivas had been recovered. The chronological sequence was in the order named. There were two forms of pit-house, of which the larger was a later development of the smaller. In each case there was a rectangular superstructure of poles with flat ceiling and sloping sides. The framework was covered with brush, leaves, etc., and a rectangular hole in the centre of the ceiling served as an entrance and smoke escape. Characteristic furnishings were a ventilator, fire-pit, a *sipapu* or symbolic representation of the mythical place of emergence, and a hole for the storage of small objects. This group of features survived in the later ceremonial chamber of the communal dwelling, a survival for ceremonial purposes of the old original type of house. The pit-houses occur in groups of four to six, perhaps representing a single family group or clan. Several might constitute a village. In some groups the central house was larger, suggesting that a definite ceremonial significance was becoming attached to a particular building, possibly representing the prototype of the kiva of later periods. The smaller houses were found to be reminiscent of structures belonging to the end of Basket Maker III. period, the larger of Pueblo I. of the Chaco Canyon of New Mexico and south-west Colorado. In general the pit-houses show a greater resemblance to dwelling forms excavated in the north than they do to those of the south and south-west. The jacal dwellings, which have upright walls of poles covered with mud and ranging from a single to several rooms, were contemporary with the large pit-dwellings.

The 'Vital' Factor in Diet.—In connexion with the letter on "Photographic Effects of Vitamins A and B", by Sophie Botcharsky and Anna Foehringer, published in our columns recently (NATURE, vol. 127, p. 856; June 6, 1931), and the note on p. 864, Dr. Chalmers Watson has sent us a paper by him on "The 'Vital' Factor in Diet: A Theory of the Nature of Vitamins", published in the *Edinburgh Medical Journal*, June 1931. He was impressed by the early experiments on rats in which it was shown that immediate and dramatic recovery was brought about when animals previously fed on abnormal diets were given a diet of bread and milk; by the capacity of irradiated milk to bring about a rapid healing of rickets in children; and by the valuable therapeutic effects of the 'Gerson' diet, which includes vegetable and fruit juices freshly prepared, wholemeal bread and milk, vegetables cooked in oil and potatoes cooked in their jackets, but with restricted amounts of meats and salt. Dr. Watson points out that the effectiveness of irradiated milk in the cure of rickets appears to be much greater than can be accounted for by its vitamin D potency as determined by tests on rats. Solar energy acts on the cells of plants and initiates the chemical energy which promotes healthy growth; this energy is passed on to the animal kingdom when the vegetable food is consumed. Artificial irradiation has the same effect as exposure to the sun's rays. The best source of vitamins is living food; much of that in common use is more or less dead or devitalised; in fact, the amount of vitamins present varies inversely with the nearness of the food to the original source of its energy. Dr. Watson considers that the plant tissues hold some of the original vital (or solar) energy which initiated the chemical changes; in other words, they are activated. When the tissues are consumed by animals or man, that energy is in turn transmitted to them as a so-called vitamin.

Ringed Plover and its Eggs.—A series of simple and instructive experiments relating to the eggs of the ringed plover (*Charadrius h. hiaticula*) has been carried out by George Marples in an area where he had more than forty nests under observation (*British Birds*, vol. 25, July 1931). When eggs were removed a short distance from the nest, the birds found them and dragged them back; but they also dragged and sat upon egg-shaped pebbles which had been painted to resemble their own eggs, although the disguising of the shape of their own eggs by the addition of lumps of plasticine did not deceive them, nor did the painting of the eggs with bright yellow, blue, and red colours. A curious observation of Mr. Hughes, that the ringed plover keeps its eggs in the positions of the cardinal points of the compass, was tested, with the result that after the deliberate derangement of the clutches in 121 cases, it was found that 80 were rearranged exactly north and south, 11 were nearly but not quite restored to the cardinal point position, and 30 clutches remained in disarrangement, north-east and north-west. Tests with various scents placed upon the eggs indicated that the birds were deficient in sense of smell (though it may be merely that the parental instinct overcame any sense objection), and the numbering of the eggs and frequent examination of their relative positions in the nest failed to prove that there was systematic rotation of the clutch, though it was clear that movement, as distinct from rotation, usually takes place.

South American Sea Stars.—Mr. W. K. Fisher, of the Hopkins Marine Station, Pacific Grove, California, describes a number of star fishes, based on material collected by Dr. Waldo L. Schmitt, of the United States National Museum, in 1926 and 1927 during an investigation chiefly of the higher Crustacea of South America in various parts (*Proceedings of the United States National Museum*, vol. 78, No. 2859, art. 15). There are some very interesting finds, especially three forms of *Anasteria* from the Falkland Islands, which, although here recorded as three species, may very likely all belong to *A. minuta*. The handsome species *Ophidiaster agassizii* Perrier is figured for the first time, two specimens having been collected in Juan Fernandez, and there are, further, very good photographs of several other species.

Japanese Dinoflagellates.—In continuation of the series of papers dealing with the fauna and flora of Mutsu Bay, Prof. Charles A. Kofoid describes the unarmoured dinoflagellates (*Report* of the Biological Survey of Mutsu Bay; Number 18, "Protozoan Fauna of Mutsu Bay. Subclass Dinoflagellata: Tribe Gymnodinioidæ". Science Reports of the Tohoku Imperial University, Fourth Series (Biology): Sendai, Japan; vol. 6, No. 1, 1930). This is one of the contributions from the Marine Biological Station, Asamushi, Amori-Ken; No. 61. These lovely organisms must be studied alive, as the usual methods of preservation destroy their characters: 33 species are recorded, including 14 which are new to science, and these are figured in three striking coloured plates, the colours ranging from pale yellow and green to pink, purple, and bright blue. A new *Nematodinium* bears large nematocysts, and there are two new species of *Pouchetia* having conspicuous eyes with complicated lenses. Prof. Kofoid's notes on *Pronoctiluca* are very interesting. The period of the prevalence of *Pronoctiluca pelagica* in Mutsu Bay coincides with that of sporulation of *Noctiluca*, and the theory that it is possibly a stage in the life cycle of *Noctiluca scintillans*, "representing the earliest stage in the life of that species before inflation by hydrostatic vacuoles", is very suggestive. *Noctiluca* itself has periods of great abundance in Mutsu Bay, especially in May and June, forming local shoals by wind action so dense that the water is much discoloured. In the same report and also from the Marine Biological Station of Asamushi (No. 19, "Notes on Recent Foraminifera from Mutsu Bay"), Dr. Yoshine Hada records 94 species and 6 varieties, 11 of the species being new to science. The paper is beautifully illustrated with text figures.

Additions to the British Coleopterous Fauna.—For a number of months past, a special feature of the *Entomologists' Monthly Magazine* has been the contributions of Mr. H. St. J. Donisthorpe on additions to the British coleopterous fauna. These articles are in the form of an annotated list of all additions made to this division of the fauna since the publication of the supplementary volume (6) of Fowler's standard work on the order. The excellent coloured plates that have appeared from time to time greatly enhance the value of these articles, and it is hoped that when the series is completed it will be available as a separate publication. The 'list' serves as an admirable example of how much work there still remains to be done, even in so well explored an order of insects as the Coleoptera, before our fauna can be regarded as having been fully studied. Many of the species, now rightly claimed as British, are only known from a single locality, or perhaps from but one or two places, and there is consequently plenty of work for the assiduous collector still to do in determining their actual ranges of distribution.

The Rift Valleys of South Australia.—The problem of the structural origin of the gulfs of South Australia and the Lake Torrens basin is discussed at some length in a paper by Dr. C. Fenner on the major structural features of South Australia in the *Transactions and Proceedings* of the Royal Society of South Australia, vol. 54. Dr. Fenner argues against the use of the term rift valley and prefers to call the features Spencer-Vincent and Torrens Sunklands, but maintains that there is insufficient evidence to support either the tension or compression theory of origin. Nevertheless, he believes that in the Mount Lofty and Flinders Ranges there is much to suggest that thrust movement and not tension has been the dominating factor. The fault block movements are generally considered to have occurred in late Miocene and Pliocene times, but there is much evidence of an intense phase in early Pleistocene and of differential movements along fault lines in late Pleistocene to recent times.

A New Uranium Mineral.—The uranium minerals of Spruce Pine, North Carolina, include a central core of black uraninite surrounded by a dark reddish brown zone, which is followed successively by brilliant orange-red gummite and an outer shell of bright yellow uranophane. The reddish brown zone has now been investigated in detail by Ross, Henderson, and Posnjak (*Amer. Min.*, May, 1931, pp. 213-220) and found to be a new mineral with distinctive chemical and optical properties and X-ray spectrum. They propose to call it *clarkeite*, after the veteran geochemist F. W. Clarke. Henderson's analyses show a composition of the type $RO . 3UO_3 . 3H_2O$. The mineral is a direct hydrothermal alteration product of uraninite, and as it is rich in soda it was probably formed during the stage of pegmatitic alteration characterised by the replacement of microcline by albite. At a later stage the solutions became poorer in alkalis and richer in silica, and clarkeite, being unstable in their presence, altered to gummite, which in turn was changed to uranophane with still higher silica and more lime and water. A reinvestigation of gummite is foreshadowed, the authors having discovered that the optical properties of the Spruce Pine gummite differ from those given in the literature.

Nitrate Deposits of California.—The nitrate deposits of southern California are generally associated with the soils resting on tilted beds of Tertiary clays and shales. A typical section shows a few inches of *caliche* underlying a layer of soil that is efflorescent below and compact above. The caliche contains most of the nitrate, though the percentage is small compared with that of the associated chlorides and sulphates. The various occurrences and the problem of origin are dealt with by L. F. Noble in *Bull.* 820 of the United States Geological Survey. Three hypotheses are considered: (*a*) upward movement of soluble salts by sub-surface moisture through capillary action; (*b*) downward movement from the soil and other surface sources; and (*c*) enrichment at the contact zone between soil and bedrock by general erosion. The last of these is regarded as the dominant process, subject to there being a sufficient quantity of saline material available, ample time for concentration, and a favourable arid climate. Although the deposits investigated do not appear to justify commercial exploitation, workable deposits of other useful commodities have been found in the course of the investigation. These include bentonite and various clays, boron minerals, strontium minerals, rock salt, gypsum, and magnesite.

Luminous Phenomena accompanying Earthquakes.—There can be little doubt that the destructive Idu (Japan) earthquake of Nov. 26, 1930, was closely associated with the lights seen shortly before, and for at least an hour after, the earthquake. They were observed by Mr. K. Musya, who collected records from about 1500 observers on both sides of the Idu peninsula, in the valley of the Sagami river, and on the shores of Tokyo Bay and the Boso peninsula (*Earthq. Res. Inst. Bull.*, vol. 9, pp. 177-215; 1931). The lights were very strong—in one place brighter than moonlight. They were usually described as bluish in colour, but sometimes as reddish yellow, yellow, or reddish blue. In shape, they resembled the rays of the rising sun, search-lights, and fireballs. The duration of each light was longer than that of lightning, and some careful observers report that the same light continued more than a minute. The directions in which they were seen pointed usually, but not always, to the epicentral region of the earthquake.

The Raman Effect.—The issue of the *Physikalische Zeitschrift* for May 15 contains an account, which extends to 20 pages, by Prof. K. W. F. Kohlrausch, of the University of Gratz, of the present position of our knowledge of the Raman effect. The author points out that Lommel in 1878 predicted the production of oscillations of frequency $n \pm w$ when light of frequency n impinged on a substance having a free frequency of w; and that the theory of the production of such oscillations was further developed by Smekell, Herzfeld, Kramers, and Heisenberg from the quantum point of view in the years 1923–25, although Raman and Krishnan were only able to establish their existence experimentally in 1928 (NATURE, 121, p. 501). After a short account of experimental methods, the author reviews the theories and deals with the structure of the undisplaced lines, the entry of rotational frequencies, the intensities of the displaced lines, and the relation between the displacement of the lines and the structure of the molecule of the substance. References to 103 papers on the subject are given.

Absolute X-Ray Wave-lengths.—Since it has been found possible to measure the wave-lengths of X-rays by diffraction from an ordinary ruled grating, there has been some doubt as to the value of the charge on an electron, which can be calculated from the X-ray data, and has appeared higher than Millikan's value. Some new absolute measurements of X-ray wave-lengths are described and discussed critically by J. A. Bearden in the second May number of the *Physical Review*. The lines measured were the K lines of copper and chromium, which are as long as can be used conveniently without an exhausted spectrometer. Gratings were used which had been ruled by Prof. R. W. Wood and under the direction of the late Prof. Michelson, and in some cases as many as eighty orders of diffracted lines were obtained. The results are of high accuracy, the wave-length of the K_β line of copper, for example, being given as 1·39225 A., with a limiting error of ± 0·00014 A., which is definitely about 0·2 per cent greater than the wave-length from crystal measurements. The corresponding charge upon the electron is $4{\cdot}806 \times 10^{-10}$ e.s.u. This could be taken to indicate that the standard value of $4{\cdot}77 \times 10^{-10}$ e.s.u. is wrong, and has at times been so interpreted. Dr. Bearden, however, now takes the contrary view, that the charge as found from the X-ray measurements is too high, and that there is a flaw in one step in the deduction of the electronic charge, in neglecting the imperfections in crystal structure the existence of which has been pointed out by Zwicky. If the difference found is entirely due to this cause, it gives in fact a precise method for determining quantitatively the magnitude of the effect in crystals, and further, if a good independent estimate of the flawing existed, the present data could be applied to the determination of the electronic charge with higher precision than has been attained by other methods.

The Jet-Wave Rectifier.—The extending use of direct current for electric traction has caused a great demand for devices which will rectify alternating current into direct current. High power rectifiers based on the valve patented by Cooper Hewitt in 1903 are widely used. The Hartmann jet-wave rectifier, which is a purely mechanical device based on interrupting a jet of mercury carrying a current by means of a tungsten knife, is also being used in practice, but they each have special fields where they do not compete with each other. In a treatise entitled "The Jet-Wave Rectifier: an Account of its Constructional Development during the Years 1919–1929" (*Danmarks Naturvidenskabelige Samfund*: *Ingeniørvidenskabelige Skrifter*. A, Nr. 24. Pp. 300. København: G. E. C. Gad. 30·00 kr.), Jul. Hartmann gives a fairly complete account of the research work carried out by the Hartmann Rectifier Co. in Copenhagen on this rectifier. The author gives an interesting account of the development of the invention. When preparing for his master's degree at Copenhagen, in 1906, he was given by Prof. Christiansen the problem of determining the velocity and the charge-mass ratio of the particles of a cathode ray using the method of deflection in a magnetic field. A few months later, when using induction coils with mechanical interrupters, he found them very unsatisfactory. Thinking over his previous work, it suddenly struck him that a mercury jet might be deflected by a magnetic field in the same way as a cathode ray, and this led him to devise the jet-wave rectifier.

Astronomical Topics.

Encke's Comet.—A letter from Mr. H. E. Wood, Director of the Union Observatory, Johannesburg, announces that he detected this famous comet a week earlier than Mr. Bobone at Cordoba; but as he did not send a telegram, the announcement of the latter arrived first. The comet was so low in the evening twilight when first photographed that part of the field of the object-glass was cut off by the wall of the dome. In spite of this, the comet gave such a strong image with eight minutes' exposure that Mr. Wood estimates its magnitude as fully 7, which is 2 magnitudes brighter than Mr. Bobone's estimate. The plates have not yet been accurately measured, but the following rough positions are sent:

1931	R.A (1931.0)	N. Decl.
June 14·7 U.T.,	$7^h\ 1{\cdot}6^m$,	15° 23′
June 16·7	7 10·8	13 38

These positions fully confirm those of Mr. Bobone in indicating that perihelion passage was about 18 hours earlier than Matkiewicz's prediction, which was June 3·84757 U.T.

This is the thirty-eighth observed apparition of the comet; it was seen in 1786, 1795, 1805, 1819 (when its periodicity was recognised by Encke), and at every return since then. The reason for the unbroken records held by this comet and by that of Halley is that their perihelion distances are small, so that they are easy objects when near their perihelion.

As a proof that Encke's comet is gradually fading, it may be mentioned that in 1865 the perihelion passage was 5·7 days earlier than in 1931, so that the conditions of observation were similar; in 1865 the comet was observed in February with instruments of moderate size; but in 1931, Prof. G. van Biesbroeck, using the powerful instruments at Yerkes Observatory, failed to obtain the faintest image of it on his photographic plates in February and March.

Impact of Stars with Nebulæ.—Mr. K. Hirayama, of Tokyo Observatory, investigates in *Proc. Imperial Acad. Japan* (7, No. 5; 1931) the effects of the impact of a star with a spherical nebula. The relative velocity is probably hyperbolic before impact, but it may be reduced by the impact below the parabolic value, in which case there will be repeated impacts, which will result in the capture by the star of part of the matter of the nebula, while the star's orbit relatively to the nebula will be reduced in size. The author suggests that the nebula might in time be so reduced and broken up as to form a system of planets revolving round the star; this is an alternative to the theory that explains the formation of the planets by the tidal action of a star passing near the sun. The paper goes on to show that a binary system passing through a nebula would have the size and eccentricity of the orbit diminished and the masses of the components increased. It also suggests that a large spherical nebula might, by capturing a great number of stars, form a globular cluster, while the repeated impacts of the stars with nebulous matter would end in the absorption of most of the latter.

Jubilee Celebrations of the Society of Chemical Industry.

THE celebration of its jubilee by the Society of Chemical Industry will long remain as a landmark in the history of both pure and applied science, and as a very convincing demonstration of the progressive narrowing of the gap between industry and pure research. The members of the Society were welcomed at the inaugural ceremony at Guildhall by the Lord Mayor of London and the Vice-Chancellor of the University of London. The close association which has always existed between the Corporation and the livery companies of the City and chemical education and research was manifested by the presentation of plaques and addresses to a number of the companies. The importance of chemical technology in this industrial age will render the meeting a not unimportant event even in the long history of Guildhall.

The first day of the celebration was marked also by the opening of the British Chemical Plant and Research Instruments Exhibition by the president of the Society, Sir Harry McGowan. A similar exhibition has not been held since 1926, and the progress made during the past five years in the application of pure metals such as aluminium, nickel, and silver, of stainless iron and steel, and of special alloys, is very striking; although it cannot yet be said that an alloy may be selected to meet any given set of requirements relating to corrosion resistance, ease of working, and mechanical strength, nevertheless such an ideal state is approaching rapidly. Methods of fabricating plant have also made strides, largely as a result of the work carried out by the British Non-Ferrous Metals Research Association on the welding of, especially, copper and special alloys; of particular interest was what is believed to be the first public exhibit of welded copper plant. Despite these developments, fused silica is still making progress and widening its scope and the size of unit available; recent productions include a valveless plunger pump, a water-driven gas injector, and a new type of lamp in which the shorter wave-length rays of the quartz mercury arc are utilised to produce ozone but are removed from the light by a filter in order to obviate danger to the eyes. New aids for the laboratory were represented by the Meta-filter, a continuously operating still for the production of conductivity water, stainless steel and iron apparatus, and a flow meter for gases at high pressure; a notable demonstration was that of the cinematographic method of studying crystal growth, which should be of considerable value to the research worker and to the industrial chemist.

A special section of the exhibition was arranged by the Chemical Engineering Group to illustrate some of the work carried on by the Department of Scientific and Industrial Research and the various industrial research associations. One of the most important advances made in physico-chemical science during the past decade or so, namely, the investigation of structure by means of X-rays, was illustrated in its technical applications by a variable anticathode X-ray tube and some forms of X-ray spectrograph designed for studying the change of structure of alloys on heat treatment and cold working, and for examining such materials as rubber and wool. Other exhibits in this section included a quartz spectrograph for the routine quantitative analysis of metals and alloys, apparatus for testing the surface conductivity of materials such as ebonite, for measuring plasticity and plastic yield, and for bringing about artificial weathering and ageing. The development of the chemical autoclave from Papin's digester of 1681 to the modern vessel, which, thanks to special forged alloy steels, is capable of being used at several hundred atmospheres pressure and at temperatures up to 450° C., formed the subject of a series of drawings and exhibits by the National Physical Laboratory. The products of high pressure synthesis shown included hydrogenation products of low temperature tar, reduction products of fluorine compounds, and a variety of condensation products.

Other activities of the Chemical Research Laboratory at Teddington, demonstrated when the laboratories were opened for inspection by the members of the Society, related to the investigation of tars, the production of synthetic resins, and to studies on the corrosion and protection of metals, and notably the protection of aluminium by anodic oxidation and of magnesium alloys by films of selenium. An attractive collection of co-ordination compounds, chemotherapeutic substances, and chemicals of historic interest, such as organic antimonials and arsenicals, were also on view.

One of the most valuable of the week's activities, and one which merits wider attention than that of those directly engaged in the relevant industries, was the discussion of a series of papers on fuel, selected by the Fuel Committee. The paper by Dr. C. H. Lander summarised the present position of Great Britain with regard to fuel supplies, and discussed the economic practicability of the hydrogenation of coal and of the production of our oil fuel requirements by this process and, to a limited extent, by pre-carbonisation of some of the coal which is now burned in its raw state. The application of hydrogenation to the treatment of petroleum residues is regarded by Dr. A. E. Dunstan, of the Anglo-Persian Oil Co., as a definite technical success, although its objective is no longer the production of petrol, but of, for example, lubricating oils from low grade stocks; the relative values of the refinery products are bound to alter in the not very distant future, when petrol is ousted from its present premier position by the development of the high-speed Diesel engine. It appears likely that a by-product industry, based on petroleum and comparable in magnitude with that based on coal tar, will become established during the next few years as a result of the increasing utilisation of refinery gases and gases obtained by cracking for the production of solvents such as glycols, esters and alcohols, and of 'anti-knock' substances; the growing demand for asphalte for road use and of carbon black for rubber manufacture is also of importance in this connexion. The future of fuel is a controversial subject, but it seems clear that the production of oil from coal in quantities sufficient to meet the demands of Great Britain is, at the moment, economically impossible; but the striking and constantly increasing yields of oil which are now obtained suggest that the processes available may compete seriously if and when oil prices rise from their present abnormally low values.

Another aspect of the same problem was presented by Mr. Taylor in his paper on the production of liquid fuels from water gas. The most promising of the many processes which have been investigated is that of F. Fischer, which yields 75–80 per cent of the calorific value of the water gas as hydrocarbons; this yield corresponds with about twenty-five per cent of the heat value of the coke required for the production of the gas. Although processes of this type resemble hydrogenation in being economically impracticable at the moment, it is probable that when the price of petrol rises, more direct and therefore cheaper methods will have been perfected. Other important papers in the fuel section included that by Prof. R. V. Wheeler on gaseous combustion, which dealt with the industrial applications of recent research work on the combustion of gases, and especially on flame propagation and the influence of diluents; and papers on low temperature carbonisation, the utilisation of low temperature tar, and fuel developments in iron and steel practice. A closely related subject, at least from the theoretical aspect, was dealt with in Prof. Wheeler's lecture on a subject of both academic interest and increasing technical importance, namely, dust explosions—delivered, very appropriately, at the Home Office Industrial Museum.

Sir Harry McGowan's presidential address dealt mainly with the reaction of scientific progress on the finance and economy of the modern State, and constituted an opportune appeal for economic unity between the nations of the Empire, for still greater unification of the various industries of each country, and for a deeper appreciation of the economic background of all industrial activity. The address by Dr. H. Levinstein, on the occasion of the presentation to him of the Society's medal, urged that the lessons to be learned from the history of the dyestuffs industry should be taken to heart by other national industries, and that the 'buy in the cheapest market' maxim should be reconsidered.

Dr. G. Engi, conveying the congratulations of the Society of Chemical Industry in Basle in an address delivered at the Salters' Hall, gave an account, in considerable detail, of recent developments in both the scientific and technical aspects of the chemical industry in Switzerland. The development of the dyestuffs industry in that country has resulted largely from fertile inventive activity and a reasonable degree of rationalisation; recent developments include the production of thioindigo dyes of the naphthalene series, of vat dyes obtained by introduction of the cyanuric ring into the anthraquinone molecule and by the synthesis of indigoid and thioindigoid derivatives of the anthracene and anthraquinone series, and of complex chromium and copper azo-dyes. Important advances have been made also in connexion with pharmaceutical products, synthetic resins, textile chemistry, and electrochemical processes. Addresses were given also by two of the new honorary foreign members of the Society, that by Dr. Sørensen dealing with hydrogen ion concentration, and that by General G. Patart with the technique of gaseous syntheses at high pressure; the development of, for example, synthetic methanol demands considerable reduction of costs, which, since the raw materials are available at almost zero cost, must be concerned mainly with the plant and equipment used. The large part played by catalysis in this type of reaction, however, necessitates improved methods of purification of the raw materials in order to remove 'poisons', and further work on the preparation of highly active catalysts. The importance of the outlets for these synthetic products justifies continued research and the expenditure of relatively large sums of money.

The very full programme for the jubilee week was completed by a series of visits to factories engaged in the chemical and related industries and to various research laboratories, and by a number of purely social functions.

H. F. GILLBE.

Congress of Universities of the Empire, 1931.

THE congress of the seventy universities of the British Empire began its official programme in London on July 1 and continued its work in Edinburgh on July 6-11. On July 3 in Guildhall—"the centre of the Empire in London, which has been for centuries a financial, and is this day an educational clearing-house of the world"—H.R.H. the Prince of Wales in his address of welcome as president of the Congress observed that "one of the things the world requires most to-day is organised knowledge and the means of distributing it". This truth crystallised in a sentence world necessities in a time of crisis. Pope said a little learning, not a little knowledge, was a dangerous thing; and assuredly in these days it is not learning which the peoples of the world require. They have enough of that from the popular press and the politician.

That millions are anxiously seeking "the two noblest things, sweetness and light" in the matter of post-War reconstruction, presented to the Empire universities an opportunity of discussion and decision on the question of the best method of disseminating organised knowledge and of promoting a closer co-ordination of their activities so as to ensure that they play their part in bringing order out of chaos. It was realised by all who participated in the work of Congress that it is in the universities, and possibly in the universities only, that the problems of to-day and the policy of to-morrow can be examined with that detachment of view, that width of judgment and that patience of understanding which alone will ensure their solution, and that these centres of knowledge must become more and more the training grounds of the young men and women who will have to do the work of the Commonwealth in the future. Lord Meston presented this point of view in another form when he said that there were certain things, essential to the well-being of their peoples, which he believed their universities were doing, which ought to be done by their universities and which could not be done systematically except by their universities. It was further realised that universities, any more than individuals, cannot live to themselves alone. The social functions—a natural and necessary part of the work of a congress of this kind—contributed to the formation of friendships, the creation of mutual understanding and trust and to that action and interaction of minds which, in Burke's words, "draw out the harmony of the universe". From every part of the Empire an instinctive desire for closer association was revealed.

Universities, however, are naturally jealous of their autonomy. Sometimes, perhaps, they are disposed to convert their conceptions of autonomy into a fetish. It is, none the less, a condition of their very existence that they should be responsible neither to individuals nor to the State for the direction of their affairs. They must develop along the lines set by tradition, by geographical accident, and by their charters. It will be a tragedy if that independence which the universities have rightly and sacredly cherished is sacrificed to expediency or to financial necessity. Not even the benefactions of the wealthy must detract from the purposes for which they have been established and which they must subserve.

The calm of the cloisters has, in these post-War years, however, been disturbed by repercussions from world politics, and in his observation that Imperial necessities demanded from the universities support of the Universities Bureau of the British Empire, the Vice-Chancellor of Manchester lifted a discussion on financial commitments out of the sphere of self-commiseration into that of bounden duty. By this one observation, the Congress was called upon to decide whether one of "the strongest and soundest links of Empire", in the Prince's words, should be the universities of that Empire.

The question of the financial support of the Bureau arose out of the proposals formulated by the executive committee of that Bureau for its reconstitution. The amended articles of association circulated for consideration by Congress were directed to the creation of a central institution which should be a genuine university organisation. Three main principles were enunciated in these draft articles: that the Empire universities should be the members of the reconstituted Bureau; that these members should pay a fixed annual subscription, the amount of which is to be determined by the members themselves acting through their representatives at the first annual general meeting held after the adoption of the articles; and that the policy and the administration of the Bureau should be controlled by a council composed of twenty-one of these representatives selected by regional groups of university representatives. In considering the proposals of the executive committee, the question that excited the greatest interest at the Congress business meeting was whether the fourteen individuals representing, but not directly responsible to, the Empire universities, who at present constitute the association known as the Universities Bureau, should continue to control and direct its administration; or whether the time has come to express a resolute faith in the solidarity of the universities of the Empire, to create an organisation which shall be truly representative of these universities, and to provide funds which will enable these members to give effect to the late Lord Balfour's policy of "promoting greater co-ordination and power of mutual consultation". A third possibility, which was indirectly raised but was rejected, was whether the Universities Bureau, which has been the creation of the universities themselves, should or should not be dissolved.

Doubt was cast by a few, dwelling in a past of fond imaginings, upon the new form of constitution, and it was even suggested that the scheme promulgated by the committee should be referred back for further consideration by the universities. It is significant, however, that Congress refused to accept this suggestion of flinging the work of two years again into the melting-pot, and satisfied the apprehensions of the ultra-orthodox with the assertion of the principle that the powers of the Universities Bureau of the British Empire should not be exercised in any such way as to restrict the powers and duties exercised by the constituent members under the several charters, statutes, regulations, and other instruments of their self-government.

This discussion finally asserted the view—a view which was unquestionably a distinctive feature of this Congress—that the Bureau has a definite place in the hegemony of Empire universities. The recognition by the Prince of Wales of the invaluable work done by the Bureau in publishing the "Universities Yearbook", a compendium which, since Sir H. Frank Heath assumed the office of editor, has become of ever-increasing value—by its administration of trusts, by its organisation of congresses and conferences, and by its centralised machinery, was affirmed by Congress itself. Indeed, during the subsequent sessions of Congress, it was frequently suggested that the Bureau might be of greater utility to overseas universities in many more directions than has hitherto been contemplated as feasible.

The addresses delivered by the Lord Provost of the City of Edinburgh, in which he hinted at the citizens' pride in their university; by the Marquess of Linlithgow, which in its insistence on the value of the trained mind was tinged with the sage reflections of an administrator; by Lord Meston, who as a layman prescribed not panaceas but useful and suggestive 'dietary' regulations and denounced illusions, claptrap and clichés, and by Sir Donald MacAlister, who from a wealth of experience warned universities of the dangers arising from overcrowding, directed attention in different ways to some of the more important questions with which universities are faced severally and collectively.

The discussions on the university graduate in commerce and industry, the Ph.D. degree, the conditions of admission to universities, general honours courses, post-graduate study in medicine and surgery, and facilities for overseas students, were all followed with interest by delegates from the universities both at home and overseas. The members of Congress had facilities provided for them to visit the Universities of Oxford, London, Reading, Glasgow, and Edinburgh, their colleges and their departments, and also visited a number of London County Council and other educational institutions, and two of the largest new schools in Edinburgh. The hospitality which was extended to all throughout their stay in London and Edinburgh has left an indelible impression of friendliness and goodwill.

This Congress will have more than served its purpose if it has helped to eradicate that feeling of isolation in which many of the overseas universities have to discharge the trust imposed upon them as repositories of organised knowledge, and to create in them a sense that the kinship of universities is not a localised relationship but is world-wide. It has also served to suggest, and perhaps this is its most remarkable achievement, that it is through a centralised agency that information of value to all parts of the Empire may best be distributed and that a community of interest may be created and maintained at full strength.

Annual Conference of the Museums Association.

THE forty-second annual conference of the Museums Association was held at Plymouth on July 6–11, by invitation of the Mayor and Corporation, who kindly placed at the disposal of the delegates the ancient Prysten House of St. Andrew's Church, now being restored under the name of the Abbey Hall. Here some two hundred delegates assembled under the presidency of Sir Henry A. Miers, whose address dealt with the recent and the impending work of the Association.

The chief event of the year has been the legal incorporation of the Association as a "company limited by guarantee", and this has led to the recognition of the Association by the Government. A directory of all museums in the British Isles, to which the public has access, has been issued. With the co-operation of the Carnegie United Kingdom Trustees, a short school for curators was held in London last October, and schools for this autumn are being organised in both London and Edinburgh; to interest educational authorities in the work done by museums in connexion with schools, an exhibition of circulating cases and collections was arranged at the London County Hall; grants to a total of £1220 have been made to six museums to aid them in reorganising their exhibited collections, and other applications are being considered; to accomplish all this work a permanent office with a paid secretary and staff has been provided."

Other matters on which Sir Henry Miers commented were "the growing magnitude and importance of the *Museums Journal*"; the discussion with the Library Association of needed new legislation for public libraries and museums; the federations of museums in Lancashire and Cheshire and in Yorkshire; the reorganisation of various museums in the direction of local education, as at Portsmouth, Salisbury, Port Sunlight, Wisbech, Norwich, and Aylesbury; and the recent visit of the secretary, Mr. S. F. Markham, M.P., to the United States. More in the future were the suggestions made by the Association to the Standing Commission on Museums; the preparation of a survey of museums throughout the British Empire, and the completion of the directory by a volume including them (this is with the help of the Carnegie Corporation of New York); the growing realisation by the educational departments of the British Government and by the World Institute of Adult Education of the educational possibilities of museums, long since realised by the Association.

The meeting was noteworthy for the increased time devoted to papers and for the animated discussions. Following the president's address, Dr. W. T. Calman, while approving modern attempts to illustrate the problems of biology, urged that on one hand they should be kept distinct from the systematic series, and on the other that there should be an exhibit definitely explaining the principles and main outlines of taxonomy. Mr. J. Bailey, formerly head of the Circulation Department at the Victoria and Albert Museum, complained that the 1924 and 1931 Loans Acts had not been put into operation, at least so far as the Bloomsbury departments of the British Museum were concerned; his view that the national treasures should be more widely lent out did not find much support from subsequent speakers. An instructive talk on "Plymouth Porcelain", illustrated by the epidiascope, was given by Mr. A. J. Caddie, curator of the Plymouth Museum. "Why do we use Plate-glass in Museums?" was the provocative title of Mr. Leney's account of his proposals for an unenclosed reconstruction of the county's natural scene in the Norwich Museum; while sympathising with their colleague's bold and beautiful dream, the practical curators present supplied satisfactory replies to his question.

On Wednesday morning an account of the Courtauld Institute of Art by its director-elect, Mr. W. G. Constable, set at rest doubts that had been raised by the letters of Lord Lee of Fareham and other notices in the daily press. A fluent and witty speech by Mr. S. C. Kaines Smith, director of the Birmingham Museum, on "Art Museum Problems", provoked much applause and some criticism. After this, "A Suggested System of Museum Registration", by Mr. K. de B. Codrington, of the Indian Section of the Victoria and Albert Museum, fell a little flat, though it was clearly the fruit of experience and careful thought; there would doubtless have been more discussion had the author not been prevented by illness from attending. The important but somewhat dry subject of paper for museum labels was made interesting by Dr. L. J. Spencer, Keeper of Minerals in the British Museum.

On Thursday, Lieut.-Col. J. M. Mitchell, secretary of the Carnegie United Kingdom Trust, expounded the principles of the Trust's action as laid down by its founder, and thus showed what kind of help museums might expect to receive; this was a revelation to many of those present. Mr. H. J. M. Maltby, of the Salford Museum, showed, perhaps unintentionally, that the "Present-Day Problems of Provincial Museums" are much the same as the problems that have vexed curators ever since the Association was founded; among them the local town council looms large.

Friday produced three very diverse papers. Mr. J. H. Iliffe, recently professor at the University of Toronto, in charge of classical archæology at the Royal Ontario Museum, spoke on "The Museum Situation in Canada", and urged the importance of personal contact between Canadian curators and their colleagues in the home country, so that the latter might realise the great diversity of outlook and the distinctness of the several regions in the Dominion. Dr. C. Hay Murray, of the Liverpool Museum, recounted his attempts at estimating the value of the Museum to the public by the length of time spent in the building by visitors; he had found that the average duration of a visit had notably increased of recent years. The final paper, an account by Mr. C. A. Ralegh Radford of the Roman remains discovered at Exeter by excavation, was a valuable contribution to archæology, with no obvious bearing on museum questions.

The only exception that could be taken to the number of papers was that they left little time for visits to museums. Members would gladly have given up the walk round Devonport Dockyard for more opportunity of studying the Plymouth Museum and the recently restored Elizabethan house. They were, however, hospitably and instructively entertained at the Marine Biological Laboratory, and were courteously received at the Athenæum, where is a museum said to be one of the oldest in the country and an excellent example of a learned society's museum in the day of our grandfathers. Too short a stay was made among the delights of Cotehele, visited by kind permission of Lady Mount-Edgcumbe. Other grateful entertainments were a luncheon offered by the Mayor, a Mayoral reception and dance at the Guildhall, and tea at the Abbey Hall on the invitation of Lady Astor, who at the annual dinner proposed health and prosperity to the Museums Association.

Imperial Sugar Cane Research Conference, 1931.

THE first Imperial Sugar Cane Research Conference, which was opened on July 20 by Dr. Drummond Shiels, M.P., is the second of these conferences of overseas research and administrative men convened by the Empire Marketing Board on a crop rather than on a science basis. The first was the Wool Research Conference held last year. The object is to get a clear picture of research in widely scattered countries, so that the gaps can be clearly seen and a general programme of research for the Empire worked out.

The Board has already made grants for research in Mauritius, where a Cane Research Station was started last year, and in Barbados, and it supports the Imperial College of Tropical Agriculture in Trinidad, where a beginning has been made in fundamental research on cane genetics. Other applications have been received, and the Board decided to consider the broad questions of research policy and of where the work could best be carried out. Besides delegates from home organisations, such as the Imperial Bureau of Plant Genetics at Cambridge (the director of which, Sir Rowland Biffen, attended the Conference), there were representatives from India, South Africa, Trinidad, Barbados, British Guiana, Fiji, Mauritius, and the Leeward and Windward Islands.

The economic position in each sugar-producing country was outlined, and this was followed by a sketch of the scope and aims of the research stations. Genetics and cane-breeding have hitherto overshadowed the other branches of research, although more attention has lately been given to the control of insect and fungus pests. Interesting details were given of the breeding work at Coimbatore, in South India, where improved varieties of the north Indian hardy cane have been evolved which are estimated to give an increased yield of 50 per cent over the ordinary varieties. Attention is now being given to intergeneric crosses with cereals which aim at reducing the ripening period. One of the Java canes, *POJ* 2725, has been crossed with *Andropogon sorghum* and the hybrid has matured in five months, instead of the normal 10-12 months, and yielded a sucrose content of 16 per cent in the juice. Equally remarkable results have been obtained with tropical or 'noble' canes (*Saccharum officinarum*) in Barbados, where the whole system of cane-breeding first originated. The Department of Science and Agriculture pots out about 16,000 seedlings a year, largely for distribution throughout the West Indies, and one variety in particular, *BH* 10 (12), is now known all over the world.

Each country, however, has its own peculiar requirements, often depending as much on economic as on climatic or edaphic factors, and has to work out its own salvation as regards varieties. But the fundamental aspect has barely been attacked in the Empire, and there is clearly a case for some central station to undertake long-range research admitted to be outside the scope of the ordinary department of agriculture.

University and Educational Intelligence.

CAMBRIDGE.—The managers of the Frederick James Quick Fund have elected Mr. David Keilin, Magdalene College, to the Quick professorship of biology for a period of three years from Nov. 1, in succession to Dr. G. H. F. Nuttall, Magdalene College, who has held the professorship since 1906, when it was founded.

W. J. Heasman, of Trinity Hall, has been appointed senior curator, and G. J. Kerrich, of Christ's College, junior curator of the Museum of Zoology.

E. E. Pochin, St. John's College, has been elected to the Michael Foster research studentship in physiology.

LONDON.—Prof. C. Burt, part-time professor of education at the London Day Training College, has been appointed professor of psychology in University College, as from Aug. 1, 1932.

The Sir George Jessel studentship in mathematics awarded to Mr. T. E. Garstang, of University College, for 1930–31, has been renewed for the session 1931–32, and a similar studentship awarded to Mr. H. Kestelman, of University College, for the session 1931–32.

IN a note in NATURE of July 18, p. 124, in referring to the reception at the new premises of Messrs. H. K. Lewis and Co., Ltd., it was stated that Prof. Thane discussed text-books; we are informed that the speaker was Prof. H. R. Kenwood, emeritus professor of hygiene in the University of London.

THE following scholarships have been awarded by the Council of the Institution of Naval Architects: Royal Commissioners for the 1851 Exhibition post-graduate research scholarship in naval architecture (1931), £250 per annum for two years, to Mr. William John Roberts, University of Liverpool; Sir William White post-graduate scholarship in naval architecture (1931), £150 per annum for two years, to Dr. J. A. J. Bennett, University of Glasgow.

SIR CAMPBELL STUART has been appointed chairman of the Beit Fellowships for Scientific Research Trust, and Sir Alfred Beit, a trustee, both in succession to the founder of the fellowships, the late Sir Otto Beit. New fellowships of the value of £250 a year tenable for two years, beginning September 1931, have been awarded to Mr. W. H. Wheeler (University of Cambridge and the Imperial College) for research on the effects of electric and magnetic fields upon gaseous explosions and detonations and to Mr. J. I. Armstrong (Queen's University, Belfast, and the Imperial College) for research on the respiration of Fungi with special regard to inorganic nutrition.

UNDER the patronage of the New Education Fellowship, a prize of 10,000 francs is being offered for the best treatise on "Total Education (Physically, Intellectually, and Morally)". Realising that the total education of an individual is conditioned chiefly by heredity and environment, the object of the competition is to emphasise the necessity of making inherited qualities the best possible, and of a careful development of such characteristics. Each individual can train himself and others in the world-wide propagation of this education, and it is essential that there should be an understanding between educationists, especially from the universal point of view. Further particulars concerning this prize competition can be obtained from either Groupe Français d'Éducation Nouvelle, 41, Rue Gay-Lussac, Paris V^e^, or the Institut de l'Entente Universelle, Terres Rouges, Toulon, Var., the latter of which remains open during vacations.

AT the British Commonwealth Education Conference which is being held at Bedford College, London, on July 24–30, under the presidency of Sir Percy Nunn, the general theme will be "Education in a Changing Empire". Native education in Africa and India occupies a considerable part of the programme of the proceedings of the Conference. The education of the non-European in Africa will be considered by the Rev. R. C. Blumer, Dr. G. G. Gillie, Miss Sara Burstall, Dr. S. Rivers-Smith, Mrs. Macgregor Ross, Mr. J. H. Driberg, and Mr. F. S. Livie-Noble. Education in India will be dealt with, under the chairmanship of Sir Phillip Hartog, by A. Yusif Ali, Fakhruddin Ahmad, and others, and the problem of bilingualism in Indian schools will be considered by Dr. Michael West. The Right Hon. W. Ormsby Gore, M.P., will give an address on "Some Education Problems of the Tropical Dependencies". Considerable attention, too, will be directed to interracial understanding, which is all to the good, showing how alive educationists are to this serious problem. Mr. H. Chaning Pearce and Miss A. Purvis will give addresses on the problem, and a discussion will be introduced by Mr. Arnold Lloyd. This subject will be closed by an address by Prof. H. J. Fleure. Among other subjects to be considered are vocational guidance, university problems in Africa south of Zambezi (Sir Carruthers Beattie), rural science and schools (Sir John Russell and others), the physical needs of children from 2 to 7 (Dr. James Kerr), growth (Prof. A. H. Harris), an Imperial Film Institute (Dr. T. Drummond Shiels, M.P., Mr. G. T. Hankin, Mr. J. R. Orr, and Prof. J. L. Myres) and modern psychology. Demonstrations of new aids to education include one by the British Broadcasting Corporation. Sir Percy Nunn will consider the question of an Imperial Institute for Education.

Birthdays and Research Centres.

July 26, 1872.—Prof. J. BARCROFT, C.B.E., F.R.S., professor of physiology in the University of Cambridge.

Until recently it was scarcely realised that an appreciable proportion of the blood in the body is not being used, except as occasion requires. Either it is side-tracked in such places as the spleen, the skin when congested, and possibly the large uterine veins of some pregnant animals, or it is 'held up' as in the liver (Maunter and Pick, Rein, Dale). Where are these depots? How long does blood remain in them? By what mechanisms is it held? For what purpose is it released?

July 28, 1864.—Prof. C. H. LEES, F.R.S., emeritus professor of physics in the University of London (East London College).

My objects of chief investigation now in progress are: The laws of plastic flow in overstressed materials; improvements in the methods of determining heat conductivities, with special reference to geothermal problems; the solubilities of gases in liquids at very high pressures, and the equilibrium of such solutions in gravitational fields; tests of theories of magnetisation with special reference to the effect of temperature on dia- and paramagnetic materials; and the solution of physical problems which arise in the study of flame propagation.

July 30, 1889.—Prof. J. KENDALL, F.R.S., professor of chemistry in the University of Edinburgh.

I am at present much concerned to find time for research in the short intervals between performance of administrative duties and attendance on committee meetings. An examination of the atomic weight of calcium contained in very old potassium-rich minerals from Portsoy and Rhiconich is, however, now being initiated. If a significant fraction of the small percentage of calcium present has resulted from the slow radioactive disintegration of the potassium, results of considerable interest in several directions may be anticipated.

Societies and Academies.

DUBLIN.

Royal Dublin Society, June 16.—**M. J. Gorman** and **H. A. Lafferty**: On a method of distinguishing the seedlings of Swedish turnip (*Brassica napus* L. var. *napobrassica* (L.) Reichb.) from those of broad-leaved rape (*Brassica napus* L. var. *biennis* (Schubl et Mart) Reichb.). Characteristic differences in the shape of the first foliage ('rough') leaf and the relative length of first internode are recognisable in the seedlings of these two plants in fourteen to twenty days from the time of sowing the seeds.—**T. Dillon** and **Annie McGuinness**: On alginic acid: its mode of occurrence and its constitution. Alginic acid cannot occur in the free state in seaweeds, since no carbon dioxide is evolved during the solution of the fronds of *Laminaria* in sodium carbonate. Dialysis of alginic acid prepared from fresh fronds gives rise to an increase in the ash-content. This suggests that in the plant the acid is combined with non-polar colloidal compounds of calcium and iron. Dry alginic acid has the formula ($C_6H_8O_6$); but this is a lactone. The polymerising unit is not an anhydride as in the case of starch and cellulose but the complete acid $C_6H_{10}O_7$. The units are therefore not pyranose or furanose rays; but open chains.—**M. Grimes** and **A. J. Hennerty**: A study of bacteria belonging to the sub-genus *Aerobacter*. The paper describes two species of bacteria previously unknown. These have been named *Aerobacter hibernicum* and *Aerobacter liquefaciens* respectively.

Royal Irish Academy, June 22.—**J. Reilly, B. Daly**, and **P. J. Drumm**: Studies in the pyrazole series—Diazotisation of aminophenylpyrazoles. The condensation of *p*-nitro phenylhydrazine and benzoyl acetone gives *p*-nitro phenyl 3 methyl 5 phenyl pyrazole, and the corresponding amino compound on reduction. This compound on diazotisation gives comparatively stable diazonium salts, and these as well as related-azo compounds have been prepared and compared.—**J. Reilly, M. Hayes, P. J. Drumm**: Lichenin. Purified lichenin has been nitrated and a compound of the type $C_{12}H_{15}O_5(NO_3)_5$ prepared. It is closely related to the corresponding cellulose nitrate.—**P. J. Drumm**: The constitution of Fischer and Bülow's pyrazole. The pyrazole obtained by Fischer and Bulow by the condensation of benzoyl acetone with phenyl hydrazine has been re-examined and found to be 1 : 5 diphenyl 3 methyl pyrazole. Evidence of the formation of the isometric 1 : 3 diphenyl 5 methyl pyrazole has not been obtained.

EDINBURGH.

Royal Society, July 6.—Clerk Maxwell Centenary: **Prof. E. T. Whittaker** delivered an address on James Clerk Maxwell and mechanical descriptions of the universe.—**J. Phillip, J. D. Scott**, and **J. Y. Moggridge**: Photochemical measurements of light intensity in two common vegetation types in tropical Africa, by means of the improved Eder-Hecht photometer. The paper records the high photochemical values registered under the light canopy of that very widely distributed woodland type, the *Berlinia Brachystegia*—other spp. community or 'Miombo'—and shows how the Bunsen-Roscoe values are correlated with duration of sunshine and with the readings of the Livingston radio-atmometer, and directs the attention of biologists to the usefulness of the Eder-Hecht photometer in the study of habitats in Nature.

PARIS.

Academy of Sciences, June 1.—The president announced the death of Eugène Cosserat, non-resident member.—**A. Lacroix**: The ægyrine nepheline syenite minerals of the north of the island of Kassa. The various pneumatolytic phases of the nepheline syenites of the Los Archipelago.—**Jules Drach**: Partial mean values and their application to the problems of mathematical physics.—**P. Villard**: The titration of phosphoric acid. Discussion of the results of Sanfourche, Cavalier, and Joly.—**M. d'Ocagne**: Remarks on interpolation with reference to a recent note by Wolkowitsch.—**Jean Baptiste Senderens**: The catalytic dehydrogenation, in the gas phase, of the fatty alcohols in the presence of pumice carrying sulphuric and phosphoric acids. Phosphoric acid has a less active dehydrating action upon alcohols in the gas phase than in a liquid system. Sulphuric acid, on the contrary, acts more readily in the gas phase.—**Georges Giraud**: The determination of tensors by partial differential equations connected with conditions at the boundary.—**G. Pólya** and **G. Szegö**: Some qualitative properties of the propagation of heat.—**S. Stoilow**: The inversion of the continued transformations of two variables.—**Gr. C. Moisil**: A system of functional equations.—**N. Aronszajn**: A remark on the singularities of Dirichlet's series.—**R. Gosse**: The integration of an equation of the first class.—**Florent Bureau**: Some properties of uniform functions in the neighbourhood of an isolated essential singular point.

—**F. E. Myard**: A closed chain with five rotoid couples, deformable at the first degree of freedom.—**E. Crausse** and **J. Baubiac**: The application of a recording method to the study of the vortices produced in liquids.—**H. Mineur, Varchon, Barbier,** and **Mlles. Canavaggia, Chevallier,** and **Roumens**: The movements of the stars as a whole.—**J. Renaux**: A new contribution to the study of the reduction of photographic negatives.—**G. Fayet**: The proximities of cometary orbits and the orbit of Pluto. From a study of 241 orbits of comets it was found that one parabolic comet and seven elliptical comets might come within the range of action of Pluto.—**Paolo Straneo**: The unitary theory of gravitation and of electricity.—**E. Estanave**: The projection in relief in space of the composite image recorded by the autostereoscopic plate.—**V. Dolejšek** and **J. Kubiček**: The complexity of the L series of barium.—**E. Huguenard** and **A. Magnan**: An ultra-rapid cinematograph giving from 2000 to 3000 images per second. The method employed consists in separating the film into a certain number of bands, each acted upon by a special objective, the various objectives working in turn at equal intervals of time. The apparatus has been applied to the study of the flight of a large fly, the wings of which were found to beat 100 times per second.—**S. Takvorian**: The search for element 61 by means of optical spectrography. These results confirm those given in a recent communication; neither the X-ray spectrum nor the optical spectrum shows any trace of element 61.—**La. Goldstein**: Atoms of recoil in the rare gases.—**Mlle. L. S. Levy**: Adsorption equilibria on previously precipitated manganese dioxide.—**E. Rinck**: Diagram of solidification of the calcium-sodium alloys. An account of a general method for determining, with satisfactory accuracy, the temperature-solubility curve of two partially miscible metals.—**M. Lemarchands** and **H. L. Roman**: The action of anhydrides upon metals. A study of the reaction between carbon dioxide and the metals sodium and potassium, and of the conditions giving the highest yield of oxalate. With potassium, at temperatures between 230° C. and 240° C., the maximum yield was 17 per cent of oxalic acid.—**Charles Baron, Charles Boulanger,** and **René Le Grain**: Contribution to the study of petrol-alcohol-benzene mixtures. A mixture of 70 per cent aviation petrol, 20 per cent benzene, and 10 per cent alcohol avoids the formation of hoar frost, possesses great stability at low temperatures, and retains the valuable properties of the alcohol-benzol mixture.—**André Chrétien**: The dielectric constant and chemical constitution. Method of measurement. As a source of current, the induction coil is replaced by a triode valve, and a galvanometer with a rectifying valve replaces the telephone as a detector. Data are given for benzene, chloroform, hexane, and acetal.—**Deluchat**: Ortho- and meta-divinylbenzenes. Ortho- and meta-diacetenylbenzenes.—**Charles Dufraisse** and **Raymond Buret**: Researches on the dissociable organic oxides: a dimethoxyrubrene. The introduction of two methoxy groups into the molecule of rubrene does not modify the essential properties of this hydrocarbon, except that the proportion of oxygen set free by the dissociation of the oxide (52 per cent of theoretical) is less.—**R. Quelet**: The monomethyl and monoethyl ether oxides of para-xylylene glycol.—**P. Carré** and **P. Mauclère**: The preparation of hydrobenzoin. The benzoin-hydrobenzoin system.—**Lespieau** and **Reginald L. Wakeman**: 1-methyl-2-ethyl-cyclopropane.—**Georges Lévy**: β-ethylnaphthaline and its hydrogenation products. Starting with carefully purified β-ethylnaphthaline, reduction with sodium and amyl alcohol gives only a dihydride: catalytic reduction with nickel gives a tetrahydride and finally a decahydride.—**St. Pavlovitch**: The transformations of braunite under the action of heat.—**F. Diénert**: Contribution to the study of the origin of subterranean waters.—**Montagne**: The yields of springs under uninfluenced régime.—**Mlle. Germaine Py**: The evolution of the cytoplasmic constituents of the pollen cells of *Vincetoxicum officinale*.—**Labergerie**: The action of oscillating circuits on the degeneration of the potato.—**F. Maignon** and **J. Guilhon**: The influence of the seasons on respiratory metabolism in the dog.—**A. Machebœuf**: Researches on the function of lipoids and proteins of the blood in the exchanges of water in the organism.—**Léon Binet** and **J. Magrou**: Glutathione, growth and cancer of plants.

LENINGRAD.

Academy of Sciences (*Comptes rendus*, No. 24, 1930).—**A. Archangelskii** and **D. Perkin**: A note on the origin of the ferrous deposits in the Lipetsk area. The deposits found in the Moscow region contain remains of *Lepidodendron* and should have been formed during the Carboniferous period as sedimentary rocks.—**N. Demjanov**: The isomerisation of the cyclic amines with the lateral chain CH_2NH_2. A brief outline of the history of the problem.—**D. Prianischnikov** and **V. V. Butkevitch**: A contribution to the physiological characteristics of potassium salts. The physiological acidity of potassium chloride is not the same for different plants; while Gramineæ, like oats and barley, absorb both potassium and chlorine at the same rate, in the case of sugar beet there is a marked excess in the absorption of potassium as compared with chlorine. Similar results were obtained for potassium sulphate.—**L. Mysovskii** and **R. Eichelberg**: The radioactivity of rubidium by observations in Wilson's camera. No definite proofs of the radioactivity of rubidium have been obtained by the method used.—**A. A. Birula**: A note on the metacarpalia and metatarsalia of *Ursus spelæus* Rosenm. In the cave bear these bones always have a shallow pit at the verticillum of the apical end. This character is absent in all recent bears, except *Melursus ursinus* Shaw.—**E. Cheisin**: Some new marine infusoria, symbiotic in molluscs of Lake Baikal. Three new genera of infusoria, *Tiarella, Ancistrina,* and *Ancistrella* found in the mantle cavity of various molluscs are described. The infusoria belong to the families Ancistridæ and Boveridæ, both known only from marine molluscs.

Comptes rendus, No. 25.—**G. Gause**: Logistic curves of the growth of the population of Leningrad and of the U.S.S.R.—**K. Nikolskii**: The geometry of the Dirac matrices.—**J. Medvedev**: The kinetics of the alcoholic fermentation. An equation is discussed which expresses the relation of the rate of fermentation to the initial concentration of the sugar and to the time.—**D. Eropkin**: The problem of studies of the solar spectrum at different altitudes above the horizon.—**N. Putochin**: α-Pyrrolidine-methylamine and the action of nitric acid on it and on α-pyrrolmethylamine. Experiments on the isomerisation of a pyrrole ring under the action of nitric acid into a pyridine ring.—**P. I. Tolmatchev**: The equilibrium in solutions of barium nitrate in nitric acid at the temperatures of 0° and 25°. The investigations proved that the solubility of barium nitrate becomes less with the increase in the concentration of the nitric acid.

WASHINGTON.

National Academy of Sciences (*Proc.*, Vol. 17, No. 3, Mar. 15).—**Elsie H. Field**: Reactions of dermal melanophores in *Necturus* to heat and to cold. As in other amphibians, the melanophores expand at very low temperatures and contract at moderately high ones; unlike those of other amphibians, they expand at relatively high temperatures.—**Stanley G. Reform of the British Patent System.*

THE need for various improvements in the British patent system has been constantly before the public in recent years, and it is generally agreed that the time is ripe for a general overhauling and lubrication of the machinery. The matter is important, for invention is closely, if subtly, connected with unemployment, and, moreover, it is chiefly through patent protection that workers in applied science can hope to win a share of the economic benefits which they confer on the community.

It is therefore satisfactory to learn, from a recent statement by the President of the Board of Trade, in reply to a question asked by Major A. G. Church in the House of Commons, that the Government proposes to take steps to prepare a Bill on this subject.

The history of the movement for reform is familiar to readers of NATURE. In October 1928 the British Science Guild published a report comprising a systematic survey of the needs of the situation, with some fifty or sixty recommendations, large and small. This was widely circulated among persons interested in the subject, and was canvassed, criticised, and mainly endorsed, in reports afterwards issued by various authoritative bodies, notably the General Council of the Bar, a joint committee representing several chemical associations, and the Chartered Institute of Patent Agents. Eventually, in May 1929, the Government set up, under the chairmanship of Sir Charles Sargant, a departmental committee, which issued its report in May last. Since the latter will presumably form the foundation of any legislation that may be introduced, a brief notice of its contents may be of interest.

The Sargant Committee appears to have used the British Science Guild's report largely as the basis of its agenda, and its conclusions, though marked in a certain degree by timidity and conservatism, are in general consistent with the policy put forward by the Guild. There can be little doubt that general support will be forthcoming for legislation on the lines proposed, if the Sargant Committee's recommendations be taken as the minimum rather than the maximum that is expected of the legislature.

The Guild's proposals were somewhat numerous. Among the more important may be mentioned the extension of the scope of the official investigation as to the novelty of inventions; extension of the judicial functions of the Comptroller of the Patent Office; a change in the tribunal for appeals from the Comptroller's decisions; strengthening of the law relating to unwarranted threats of patent litigation; and the institution of a system of cheap short-term patents of narrow scope, analogous to the German *Gebrauchsmuster*. The Sargant Committee rejected the last of these proposals outright, for reasons which are stated fairly and at some length in its report. The evidence tendered before the Committee was rather evenly divided for and against the proposal, and the decision is probably right. Short-term patents would bring advantage to some sections of the community and disadvantage to others, and legislation on such a complicated and uncertain subject would not be justified unless an overwhelming demand for it had followed the British Science Guild's report. Such a demand has not arisen. In view, however, of the German practice, it is well that this proposal should have been thoroughly thrashed out.

---

* Board of Trade. Report of the Departmental Committee on the Patents and Designs Acts and Practice of the Patent Office. (Cmd. 3829.) Pp. 104. (London: H.M. Stationery Office, 1931.) 1s. 6d. net.

As regards the proposed extension of the Comptroller's jurisdiction, the members of the Sargant Committee were divided among themselves. The object of the British Science Guild's suggestion on this head was to provide a way out of the impasse which arises from the high cost of patent litigation and the difficulty of obtaining a suitable arbitrator in many patent disputes. In effect, only the wealthiest corporations can afford to enforce their patent rights or to defend themselves against an action for infringement; for such actions have to be tried in the High Court with the assistance of expensive expert witnesses and of counsel who are capable of dealing with scientific technicalities: thus, for the great majority of those who are entitled to justice in connexion with patents, justice is inaccessible on account of its high cost.

The British Science Guild proposed, as a partial solution of this difficulty, that the Comptroller of the Patent Office should be authorised to deal with infringement actions by consent of the parties. This proposal, together with modifications of it, was rejected by the majority of the Sargant Committee; but although a minority report was not formally appended, the fact is mentioned that "a substantial minority has been so impressed with the desire and the need for providing some less costly method of settling disputes relating to patents that it would like a trial to be made of an extension of the jurisdiction of the Comptroller for this purpose". The reasons underlying the opinion of the progressive minority are convincingly stated, while the reasons given for the majority opinion amount in large part to a mere description of prejudices of the kind which are known to be directed against innovations in legal practice. The general question of the high cost of patent litigation is waived, as lying outside the Committee's terms of reference; but for our part, we fail to see why there should be at present no prospect of "the immediate constitution of a special Court to deal with disputes relating to patents and other forms of industrial property, with a view to working out a cheaper and speedier method of trying such disputes". A change in the High Court of that character is undoubtedly desirable and practicable. The majority are content, therefore, to leave without attempted remedy what is probably the most serious of all the defects of the existing patent system in Great Britain.

Appeals from the Comptroller's judicial decisions are at present heard by one of the Law Officers of the Crown, and the British Science Guild recommended that these officers should be replaced by a special judge sitting in chambers. This recommendation was adopted by the Sargant Committee in a slightly modified form. The procedure would be as at present, but a judge selected by the Lord Chancellor would be substituted for the Law Officer.

With regard to the protection of manufacturers against unwarranted threats based on alleged patent rights, the Sargant Committee goes somewhat further than the Guild thought it politic to suggest, and there is clearly a strong case for drastic legislation in the sense of the recommendation made. The effect of this would be that when a person, claiming to possess patent rights without really being entitled to do so, threatens to take legal proceedings for infringement against a manufacturer or his customers, either the manufacturer or his customers would be able to carry through an action against the threatener, so as to get an injunction to restrain him and to recover damages. At present this obviously just proceeding is obstructed by certain legal provisions of a somewhat technical character, the result of which is, in particular, that makers of seasonal goods sometimes lose their market for a year, without remedy, in consequence of threats for which there was no legitimate foundation.

At present the Patent Office examiners make a search among British patents not more than fifty years old, to see how far the inventions that come before them are really new. This restricted search was instituted as an experiment more than a quarter of a century ago, and it is very generally felt that, since the experiment has yielded satisfactory results, the time is ripe for the system to be carried to its logical completion: that is to say, that the Patent Office search should no longer be restricted to British patent specifications, but should comprise other relevant technical documents. The only obstacle is a financial one, for such an extension of the search would cost a good deal of money. The British Science Guild pointed out that the necessary funds are already available in the excess of fees taken every year from the pockets of inventors and used as revenue by the Exchequer, which adopts this singular method of encouraging the inventions on which the progress of industry depends.

The annual surplus of the Patent Office budget is steadily increasing, and for the year 1930 amounted to no less than £154,545. There are indications in the report that the Sargant Committee was sensitive to Treasury opinion in dealing with this subject; for while the members declare in paragraph 404 that "the subject matter referred to them is an essentially technical one, and questions of finance lie outside its proper limits", the Committee does not dare in paragraph 47 to recommend any extension of the search that would cost more than £60,000 per annum, and even of this sum two-thirds is to be raised by an increase in the fees paid by inventors. Reading between the lines, one can guess that if the matter had been decided on technical considerations alone, without reference to financial restrictions, the Committee's recommendations would have gone considerably further. But in these hard times we must be thankful that the Committee had even that much courage, and the somewhat parsimonious improvement recommended by it will at least be a step in the right direction.

The report contains a number of minor recommendations, which are generally in harmony with the recommendations of the British Science Guild and will, if adopted, enable the patent system to work more smoothly. It discusses also two important questions which were brought before it not by the Guild but by the Joint Chemical Committee and the Patent Office. The first of these was the 'dedicated patent' scheme. This was intended to take account of a tradition held by the medical profession to the effect that, while it is legitimate to accept fees for administering new drugs, it is illegitimate to accept patent royalties for inventing them. In an attempt to reconcile this tradition with the interests of chemical research and invention, the Joint Chemical Committee suggested that medical patents should be compulsorily dedicated to the public and administered by a State department, which should allocate a fair profit to the patentees. The medical profession, after some wavering, showed itself hostile to this scheme, and the Sargant Committee, while reporting adversely upon it, evinced a feeling that medical inventions may quite legitimately be patented in the ordinary way.

The other important new point was somewhat technical, and related to Section 32A of the Patents Acts. Briefly, it may be said that prior to 1919 the invalidity of a single one of the claims which define the scope of a patent was enough to damn the whole patent; but the Act of 1919, in remedying this hardship, made way for an abuse by removing the danger which a patentee had incurred if, in defining the scope of his monopoly, he had tried to cast his net unreasonably wide and to claim more than he had really invented. As a result, there has grown up a bad practice of using unconscionably wide verbal formulæ in patent claims, and the Sargant Committee proposes that this abuse should be checked.

The findings of the Sargant Committee represent the irreducible minimum of reform that will content those who desire to bring the British patent system up to date. The chief danger is that the technical character of the whole subject may blind the public and the legislature to its importance, particularly when parliamentary time is subject to such keen competition on behalf of controversial and party legislation.

Hamilton's 'Characteristic Function'.

The Mathematical Papers of Sir William Rowan Hamilton. Vol. 1: *Geometrical Optics.* Edited for the Royal Irish Academy by Prof. A. W. Conway and Prof. J. L. Synge. (Cunningham Memoir No. 13.) Pp. xxvii + 534. (Cambridge: At the University Press, 1931.) 50*s.* net.

THE publication of the mathematical papers of Sir William Rowan Hamilton, to whom no one will deny the title of greatest of Irish mathematicians, is a notable event. This is the first of the four volumes which are expected to be published, and the only regret that its appearance can arouse is that it did not appear until sixty-five years after Hamilton's death and more than a hundred years after some of its contents were written.

Hamilton's name is known to most students in connexion with the general equations of dynamics and more particularly to students of quantum and wave mechanics, and there are probably comparatively few but the specialists who realise what a remarkable man he was, or that his dynamical theorems were a development of his work in geometrical optics.

The volume before us opens with an *éloge* delivered by the president of the Royal Irish Academy, the Very Reverend Charles Graves, in 1865, shortly after Hamilton's death. This gives an interesting review of the life and work of a man of very great distinction. To quote one passage only, it is said that " he was to the last degree solicitous about the metaphysics of every subject on which he undertook to write . . . this was in accordance with his views regarding the ascending scale of the subjects of human thought. To religion he gave the highest place, and this not as a formality; for his was a deeply reverential spirit. He assigned the next to metaphysics. To them he subordinated mathematics and poetry, and assigned the lowest place to physics and general literature." His literary attainments were of a high order and he was on terms of friendship with Wordsworth, Southey, Coleridge, and many other distinguished writers of his time.

The present volume is a monument to Hamilton's powers as a mathematician and the vast amount of his original work. We learn from it that the number of his note-books in the library of Trinity College exceeds two hundred, in addition to unbound manuscripts; that they " contain memoirs on a variety of subjects, complete in themselves, and carefully elaborated . . . ", and the author of the *éloge* expressed the hope that they will yet see the light. Of Hamilton's youth, he records that he was born in 1805 and entrusted at the age of three to the care of his uncle, the Rev. James Hamilton, of Trim, under whom he studied until he entered Trinity College in 1823; that he communicated his first paper, " On Caustics ", to the Royal Irish Academy in 1824; and that while still an undergraduate of twenty-one he was elected to be professor of astronomy in the University of Dublin and Royal Astronomer of Ireland.

With our curiosity further aroused by the fact that by the time he was twenty, this young man had added the " Characteristic Function " to the sum of human knowledge, we turned to his biography (by the Rev. R. P. Graves, 3 vols., 1882 . . .), there to learn something of the early education which had made such developments possible. His uncle was a schoolmaster, and a very capable one. By the time he was four and a half years old, the child was reading Latin, Greek, and Hebrew; at eight he had added French and Italian, and before he was ten he was working at Persian, Arabic, and Sanskrit and reciting Dryden, Collins, Milton, and Homer. At eleven he compiled a Syriac grammar; and withal he was a very human boy, swimming with his uncle, 'riding the ass', and 'making small pits for the workmen to fall into'. It was no doubt an advantage that he acquired a zest for languages before beginning the study of mathematics, for though he carried on his classical studies as an undergraduate and won prizes for English verse and the highest distinction in Greek, yet if mathematics had caught him earlier he might have missed some of that love of literature which was to be a permanent enjoyment throughout his life.

Hamilton appears to have begun Euclid and algebra at about ten; at fourteen he was studying optics and astronomy, and making observations of eclipses and occultations on his own account. A little later he was at work on Newton's " Principia ", Garnier's " Differential Calculus ", and the " Mécanique céleste " of Laplace; and at seventeen he asserted that he would " rather have the fame of Archimedes than of his conqueror Marcellus or than any of those learned commentators on the classics, whose highest ambition was to be familiar with the thoughts of other men ", and began forthwith to write a paper on " Systems of right lines in a plane "; a paper which, as he said many years later, contained the germ of his investigation respecting systems of rays.

At eighteen, Hamilton entered the University, and within a year he had a paper ready for publication. Its title was " On Caustics ", and it is printed for the first time in the volume before us. It is a remarkable production for a boy in his teens. It deals with the properties of a general rectilinear congruence without special reference to optics and with no reference to the characteristic function. The editors note an error—a cusp-locus mistaken for a singular solution, an error which Lagrange also appears to have made—and they elucidate it at length in an appendix. The paper was presented to the R.I.A., but was not published. The referees, though impressed by its novelty and by the analytical skill displayed in it, were cautious, and in a friendly report asked for the analytical processes to be more fully developed before publication.

Hamilton continued his investigations on a more definitely optical basis and in the next two years produced a new paper, greatly enlarged in scope, which was presented to the Academy under the title "Theory of Systems of Rays" and published in 1827. This paper with its three supplements fills more than half of the present volume and is of itself sufficient to establish Hamilton's fame as a mathematician. The 'characteristic function' is introduced at an early stage and at once becomes the basis of the theory. The first part of the paper deals with ordinary systems of reflected rays, and the second part in a similar way with refractions. The geometry of the general normal congruence is extensively developed and there are lengthy discussions of aberrations and of the density of reflected light. The second part concludes with the application of the calculus of variations to the characteristic function to deduce the path of a ray in a medium of continually varying density. This second part of the paper is now printed for the first time.

The "First Supplement" (1830) introduces us somewhat abruptly to Hamilton's function W applied to straight rays in a homogeneous medium. It is a function of the direction cosines of the final ray, whose form is determined by that of the characteristic function V considered as a function of the co-ordinates of a point on the ray. In a useful appendix the editors direct attention to further aspects of the function W, in particular in relation to tangential co-ordinates.

The "Second Supplement" (1830) shows that W (an arbitrary function of the direction cosines of the final ray) furnishes a general integral of the differential equation

$$\left(\frac{\partial V}{\partial x}\right)^2+\left(\frac{\partial V}{\partial y}\right)^2+\left(\frac{\partial V}{\partial z}\right)^2=\mu^2$$

satisfied by V in an assigned medium; and introduces a further function U, a modified characteristic function which was used by Lord Rayleigh in his paper on "Hamilton's Principle and the Five Aberrations of Von Seidel" (1908).

The "Third Supplement" (1832) represents a great advance. It is a generalisation and extension of the previous work to include the case of heterogeneous and anisotropic media. It includes variations of the initial as well as of the final elements of the ray, and adds a term to the characteristic function to provide for variations in colour. It introduces the second auxiliary function T, applies the methods to the wave theory as well as to the emission theory, and contains the remarkable theoretical discovery of *conical refraction*.

Part II. of the volume contains, in some fifty pages, reprints of ten minor papers dating from 1832 to 1841, all of which are of interest, particularly so a British Association Report "On the Characteristic Function in Optics". Part III., "Manuscripts", consists of papers not hitherto published, including the original paper "On Caustics" and a lengthy paper "On the Improvement of the Double Achromatic Object Glass".

In addition to Hamilton's papers, the book also contains an excellent introduction, which traces the development of the characteristic function as it gains in generality and power through the various papers that follow, and sums up Hamilton's achievement in the general theory of geometrical optics. The editors also direct attention to the value of Hamilton's work from the purely geometrical point of view, and indicate that Kummer, who is often regarded as the founder of the theory of the general rectilinear congruence, was careful to give full credit to the work of Hamilton; they also remark that Hamilton not only developed the theory of the congruence in his paper "On Caustics" but even attacked its singularities. The introduction to the book also contains a brief summary of the contents of all the papers that follow.

The volume closes with some fifty pages of "Editors' Appendix", containing historical notes and references and notes explanatory of difficulties in the text, where the argument is unnecessarily prolix or where it needs amplification. Indications of the relation of Hamilton's work to modern mathematics are also given. This is a very valuable part of the volume. It affords evidence of the thoroughness and the great amount of care that the editors have expended on the work, and is deserving of the gratitude of all students of the subject and, indeed, of all who desire to see Hamilton's papers published in a form befitting their merit and the greatness of their author. There is no gainsaying the fact that though Hamilton's style is lucid and attractive, his ideas are not always easy to follow to their conclusions, and, to quote the editors, "the application of his methods to the optical instrument of revolution was for long the despair of mathematicians". There is little enough of application of the theory to be found in the papers, and it is a matter for regret that Hamilton did not complete the book to which he refers in a letter of 1841 (quoted in his biography): "I am seriously thinking of publishing after some months a treatise on Optical Systems of Rays, for University men and others of that class, and have several times recomposed the first mathematical chapter. . . . My object will be to make better known my method, and especially to show that it *is* a *method*, an *instrument* of demonstration and research." The book was never published, and it would be of interest to know whether the manuscript is among the many in the library at Trinity College, Dublin.

It is curious that while Hamilton's work on optics was well known in Great Britain and the use of the characteristic function in optics was the subject of a number of papers by Maxwell and others, it remained almost unknown in Germany for the best part of a century. In 1895 a paper, "Das Eikonal", was published by H. Bruns announcing his discovery of the characteristic functions for homogeneous isotropic media, naming them the Eikonal, and making what was in the circumstances a singular claim, that the Eikonal which he had discovered plays, in the narrower region of geometrical optics, a similar rôle to that of Hamilton's theorem in mechanics. The theory of the Eikonal was more fully developed by Schwarzschild in 1905 and has been used by several modern writers. But the editors direct attention to the valuable appreciation and review of Hamilton's published papers on geometrical optics in two papers by G. Prange in 1923, and to the 1924 edition of Czapski-Eppenstein, "Grundzüge der Theorie der optischen Instrumente", in which, for the first time, the work of Hamilton has received adequate notice in a compendious textbook.

In conclusion, the editors are to be congratulated on the publication of so much of Hamilton's work in so attractive a form, and on the production of a volume which reflects so well the care they have bestowed upon it.

In the printing of the book, the standard of excellence associated with the Cambridge University Press is well maintained.

A. S. RAMSEY.

Soviet Science.

Science at the Cross Roads.[1] Papers presented to the International Congress of the History of Science and Technology held in London from June 20 to July 3, 1931, by the Delegates of the U.S.S.R. Pp. iv + 23 + 4 + 24 + 12 + 12 + 10 + 4 + 31 + 62 + 15 + 3. (London: Kniga (England), Ltd., 1931.) 10*s.* 6*d.*

THE file of black-bearded men who marched across the room at South Kensington at the opening meeting of the recent International Congress of the History of Science was one of its most striking features. They were delegates from Russia and had arrived from Moscow by aeroplane. It was the largest deputation which appeared together at that reception from any country except the United States. Finding later that no one speaker could be allowed more than ten minutes to develop his subject, they decided to have their speeches printed and published in London, and this was done in what is probably the record time for a volume bound in cloth and lettered in gold. It appeared on the seventh day after they had handed their manuscripts to the printers, and it was reviewed in at least one weekly journal two days after. The story is typical of the feverish speed with which the work of reconstruction is going on in present-day Russia, and one can only hope that what is being done in such haste will not be repented at leisure by the masses who are undergoing the process.

The book before us will be read with mingled feelings, sometimes of admiration for the grandiose ideas and the energy with which they are being applied in virgin soil, often with puzzlement as to the meaning of certain abstract phrases which are constantly used in connexion with well-known facts in the evolution of science, often again with irritation at the ceaseless repetition of catchwords which no fair-minded student can think have any real bearing on the subject under discussion. The last class of instances will probably be most obvious to the average English reader and can be dealt with most easily. The essays refer constantly to "bourgeoise" science and "science in capitalist societies" and the revolution to be effected in science by "dialectical materialism". Throughout there is the implication that science before the Russian Revolution, even if not entirely due to capitalist contrivance, had certainly been used for capitalist ends.

On this point a clear and simple distinction may be made. So far and so long as industry is in the hands of private producers, the discoveries of science will be used by those persons for the improvement of their processes. The first effect, if the science is sound and the applications practicable, will be to increase their profits, though the advantage will be gradually distributed throughout society according to the economic and moral relations existent in it. Hence, no doubt, the primary result of the applications of science in the nineteenth century was the creation of a large comfortable middle-class, based on scientifically organised industry. But this development is immediately followed by a diffusion of the gains—through social reform, cheaper prices, trades unionism, etc.—among society as a whole. We therefore have at the present time, in all the most fully industrialised countries of the West, a population largely and demonstrably better off than they were before the Industrial Revolution. Whether the Russian method will in the end secure the same, or even superior, results remains to be seen; up to the present it certainly has not.

When we come to speak of science in itself, that is, the systematised and tested knowledge of the world we live in, the attempted distinction between a 'bourgeoise' and a 'socialist' science is irrelevant and absurd. The laws of Nature are the same for all of us, and they have been built up by the co-operating efforts of men of all nations, classes, and opinions. No one, in all the millennia which have seen this process going on, has ever before suggested that there was one type of truth about Nature produced by, and useful to, those in a privileged position in society, and quite another type to be revealed to those who approach it under the orders of a socialist government. Such a government might indeed make better use of the gifts bestowed by science than have certain governments in the past, but it could not discover different laws. It might by generous encouragement lead its subjects to build up the fabric of science more quickly. If Russia does this, all the world will be her debtor, just as she is in debt to all the past and all the nations—'capitalist' or otherwise—who have given her, and are still giving, the fruits of science which she enjoys.

The slogan which is thus dinned into our ears is, of course, of political origin and derives from the fundamental statute of the Russian universities under the Soviet Government. This lays down that "The Academy has to contribute to work out a unique scientific method on the basis of a materialistic world view, directing the whole system of scientific knowledge toward answering the needs of social reconstruction". Here again we must distinguish the element of truth from the large and dangerous fallacy. It is well to make more prominent than the past has done the need of reconstructing society on a scientific basis; it is fatal to attempt to limit the free use of their powers by those who have to lay the theoretical foundations.

Of the papers submitted to the Congress, the most interesting and learned is that by Bukharin, director of the Industrial Research Department of the Supreme Economic Council. His reading is immense and varied, and he uses it to illustrate his two main theses. The first is that all knowledge is a social product and is inseparably connected with practice, "for every man experience, representing the result of the influence of the external world on the knowing subject in the process of his practice, stands on the shoulders of the experience of other people. In his 'I' there is always contained 'we'." This is all excellent and clear. The latter part of his paper is less so, for it involves that identification of the movement of scientific opinion with social revolution which is continually repeated as 'dialectical materialism'. This is the crude legacy which Marx inherited, or claimed to inherit, from Hegel, and it lies heavy on the shoulders of these men who are striving, many of them with genuine and disinterested enthusiasm, to make a success of their experiment and raise the lot of the millions of Russia.

Of the remaining papers, two will attract most attention and add something notable for our information or inquiry. One is the paper by Vavilov, president of the Lenin Academy of Agricultural Sciences. It gives, in summary form, the results of inquiries carried out in different parts of the world as to the origins of agriculture. Expeditions have been sent out and results tabulated as to seven or eight primary agricultural centres, both in the Old World and the New. Great stress is laid on Abyssinia, and some curious and valuable facts appear to have been discovered there as to the early cultivation of wheat, flax, barley, and coffee. Vavilov concludes that Egypt borrowed its crop plants largely from Abyssinia, and that the primary agricultural centres generally are in tropical and sub-tropical mountain regions.

The other paper which will lead to further inquiry is that of Prof. M. Rubinstein on the recent development of institutions for scientific research. Of these there has been a large increase, especially in the last few years. In 1930 there were 72 scientific research institutes, with 83 branches, as against 24 with 8 branches in 1928, with thousands of factory laboratories, and a personnel of 'workers' given as 40,000 and students (in 1931) as 157,000.

It is evidence of amazing zeal and energy, whatever may be the quality or permanence of the work. Our visitors, and those who sent them, should rest assured that we have in Great Britain nothing but goodwill for all genuine efforts to advance knowledge and spread its beneficent results over the widest area. We plead only for that tolerance and goodwill which are ready to recognise similar merits, wherever they may be found and under whatever government. For science, being the common offspring, should be the common link of all mankind.

F. S. MARVIN.

Aeroplane Survey of Peru.

Peru from the Air. By Lieut. George R. Johnson. With Text and Notes by Raye R. Platt. (Special Publication No. 12). Pp. xii + 159. (New York: American Geographical Society, 1930.) 5 dollars.

THE value of aeroplane photography and surveying has been well demonstrated in archæology and forestry, and its special service to the geography of rugged and waterless countries is illustrated by the volume of photographs of Peru, taken by Lieut. G. R. Johnson, when chief photographer to the Peruvian Naval Air Service, and issued by the American Geographical Society. The volume includes 150 well-selected photographs, each 8½ in. by 6½ in., and six sketch maps. It has an excellent introduction by R. R. Platt, head of the Department of Hispanic-American Research of that Society.

The geographical structure of Peru is still inadequately known, owing to the difficulties imposed by the waterless nature of most of the coastal plain and the almost chronic rains and the labyrinth of deep and densely forest-clad valleys in the Eastern Andes. It consists of three geographical units: the coastal belt, the Andes, and the upper valleys of the Amazon. The essential structure of each of them is still imperfectly known or has been, until recently, misunderstood. The Andes form the backbone of the country and they were regarded as composed of two fold-mountain chains separated by the great basin which contains Lake Titicaca. The Western Cordillera have been found to be a high plateau, of which the surface is a peneplane cut across the folded strata; the western front is dissected by profound canyons, the irrigated floors of which include the most productive areas in Peru. Some of these valleys are continued across the coastal belt and their crops of cotton and sugar are exported from the thirty ports that occur isolated in the coastal desert. The southern coast is bordered by an ancient mountain chain which has been called by Steinmann the Chimu-Andes.

As the photographic survey was conducted by the Peruvian Naval Department, the coastal belt is naturally the best illustrated, with numerous views of the deeply indented northern coast, the guano-capped islets and peninsulas, the ports and the valleys they serve, and the dunes and deserts that sever overland communication along the coast. The peneplane of the Western Andes is graphically portrayed and there are striking photographs of the lofty extinct volcanoes that rest upon it.

The eastern valleys are relatively neglected. The illustrations are of the riverside hamlets an the hydroplane stations on the upper tributaries o the Amazon. They show that the development o eastern Peru has made less progress than might b inferred from the ordinary maps. The volume doe not illustrate the structure of the Eastern Andes, a it does that of the coastal belt. The nature of th front of the Andes above the Amazon is uncertain it has been often regarded as a dissected fault scarp but that view is denied by Dr. Bowman. A serie of aeroplane photographs of the area might affor the easiest solution of this problem, but the fe views of the Eastern Andes were selected to illustrat the settlements in the valleys and not the geneti structure of the country. The volume will be most useful companion with current literature o Peruvian geography.

Short Reviews.

Contributions to Marine Biology: Lectures an Symposia given at the Hopkins Marine Station December 20–21, 1929, at the Midwinter Meetin of the Western Society of Naturalists. Pp. viii + 277. (Stanford University, Calif.: Stanford University Press; London: Oxford Universit Press, 1930.) 35*s.* net.

THE growth of marine stations on the Pacific coas of the United States has induced much experimental research on the biology of organisms an the nature of their environment. The Wester Society of Naturalists has instituted mid-winte meetings where this is discussed, and the presen volume contains 23 papers presented in 1929. The commence with a most thoughtful lecture by C. A Kofoid on the "Evolution of the Tintinnoinea" a group of pelagic ciliates, which he has monographed. They possess an external chitinoid shell formed perhaps by both daughter cells after fission The species in a genus are characterised by increas in size, duplication of structural features, elongation, and differentiation of surface pattern. Undigested fæcal residues may be built into the shells and there is a beautiful picture of the utilisatio of coccoliths for this purpose. The known specie in polar waters is 101 and in the tropics 515, whic approximates to the requirements of Van 't Hoff' law. It is suggested that solar radiation is the on outstanding factor capable of inciting genetic chang in these animals. Another lecture was given b T. Wayland Vaughan on "The Oceanographi Point of View". Then follow 21 papers divided into oceanography, permeability, photosynthesis early development, marine Algæ and growth.

We admire the quality and keenness of th writers, while in some cases desiring that the research had been further extended before publication. We are pleased to see researches on the livin green and brown Algæ from Stanford and Seattl Universities, and a thoughtful article by A. R. Moore, in which it is claimed that cell-bridges ar necessary to account for the arrangement of the cells in the formation of blastula and gastrula. As general propositions, not necessarily applied to the papers in this volume, we suggest that no research be published without an adequate summary, and that an author is not entitled to cite any literature which he has not personally consulted without stating this fact.

Outlines of Palæontology. By Prof. H. H. Swinnerton. Second edition. Pp. xii + 420. (London: Edward Arnold and Co., 1930.) 21*s.* net.

It is a good sign that a second edition of this excellent book should be called for after seven years, a period which for text-books of this rather special character must be regarded as short. For this is far removed from the ordinary manual. It is no mere summary of either facts or theories. While it does not ignore facts, it bases on them a succession of thoughts that breed thought in the reader. Prof. Swinnerton has not compiled facts, he has assimilated them, and every page bears the mark of an original thinker.

While welcoming a second edition, we feel it our duty to say that the revision has not been so extensive as to provoke any student to exchange old lamps for new. Several obvious misprints have been corrected, but others only partially or not at all. *Saccemina*, for example, has had the *e* changed to *a*, but does not yet attain the perfection of *Saccammina*. Some erroneous or inexact statements of the first edition have been modified, but not always quite successfully, and this clearly has arisen from a desire not to alter the standing type or stereo-plates more than was necessary. Thus, on p. 141, there is an ingeniously contrived improvement in the account of the crinoid centrodorsal, but the distinction between that structure and the proximale is still incorrectly given. Several statements or expressions that we should like to have seen altered, remain as they were. Prof. Swinnerton is entitled to his own opinion; but some of them are more of fact than interpretation. Among these, the diagram showing the relative abundance of the echinoderm classes in time certainly should have been re-drawn to-day, whatever may have been thought of it in 1923. Let us hope for a third edition in 1937. F. A. B.

Chemistry for Matriculation. By Dr. G. H. Bailey and H. W. Bausor. Third edition. Pp. viii + 448. (London: University Tutorial Press, Ltd., 1931.) 7*s.* 6*d.*

The aim of this class-book is to present a clear account of the essential principles and phenomena of elementary chemistry. The subject is divided into three sections. Section 1 is of an introductory nature. The earlier chapters are concerned with the study of such common substances as air, water, chalk, and the acids, bases, and salts. In the later chapters of this part, the fundamental principles and theories are deduced and outlined. This section concludes with a description of the phenomena of electrolysis and with chemical calculations. Section 2 consists of a lengthy systematic treatment of the non-metals and their more important compounds, whilst Section 3 deals similarly (but more briefly) with some of the metals.

The authors have endeavoured to keep the treatment of the subject as practical as possible, and have introduced many simple experiments to illustrate the facts and support the general theories of the science. Sufficient details are generally given to enable the student to carry out the experiments unaided. Compared with previous editions, the subject matter of the book has undergone considerable revision and rearrangement, whilst additional information has been given, especially in connexion with industrial practice. Opinions differ concerning the most suitable methods of treating elementary chemistry; but as a text-book for candidates reading for university matriculation examinations, Bailey and Bausor's volume attains its object.

Aus der Medizin des Rinascimento. An der Hand des "Leben von Benvenuto Cellini" nach der übersetzung Goethes. Von Prof. Dr. Paul Strassmann. Pp. 56. (Leipzig: Georg Thieme, 1930.) 13 gold marks.

This fine volume contains a commentary on the passages in Goethe's translation of Cellini's autobiography which throw light on the medicine of the Renaissance. The close relationship between the artists and anatomists of the period, of which Leonardo da Vinci offers the best-known example, is well illustrated by Cellini, who counted among his friends Guido Guidi, otherwise known as Vidus Vidius, of Florence, and Berengario da Carpi, of Bologna, who, in addition to being highly skilled surgeons, made valuable contributions to anatomy.

Several pages are devoted to a consideration of Cellini's illnesses, which included malaria, from which he suffered on several occasions; brass founders' ague, contracted while he was engaged on the statue of Perseus at Florence; a protracted fever, accompanied by delirium, which may have been typhoid; and a disease regarded by some authorities as syphilis, though this view is discredited by Strassmann; as well as an almost fatal attack of arsenical poisoning. The other points of medical interest discussed in this book are the prevalence during the Renaissance of syphilis, prostitution, and homosexual practices; the high incidence of illegitimacy, the position of contemporary obstetrics, and the high maternal and infantile mortality.

The text is interspersed with numerous excellent illustrations relating to Cellini and the medical life of his age.

The Human Body. By Dr. Logan Clendening. Second revised edition. Pp. xiv + 399. (London and New York: Alfred A. Knopf, 1931.) 10*s.* 6*d.*

It is refreshing to meet a book like this, which is at one and the same time enlightening and entertaining. It contains a fund of common sense, and the passages on dyspepsia and constipation ought not to be missed by present-day food faddists. It represents a pleasant means of obtaining much information about the inner workings of the body.

Stresses in Wheels.

By Prof. E. G. COKER, F.R.S.

THE stresses imposed on wheels during construction are usually not inconsiderable, and the loads, borne by them later, add greatly to the stress intensities. Although wheels are in universal use, comparatively little appears to be known of the stress distributions in them, although long practical experience has enabled constructors to satisfy exacting modern conditions.

In the vast majority of cases a wheel is built up with a central hub connected by spokes to a circular rim, a combination usually known as a wheel centre, on which is secured an outer tyre. Until the bicycle era, spokes were almost always in compression, and the invention of the wired wheel with all spokes under considerable tension was a notable advance in construction for light vehicles. Modern conditions, however, appear to favour the use of the older form for all heavy traffic, with a well-marked difference between wheels for road and rail vehicles, in that for the former the wheel almost invariably revolves on a fixed axle, while for the latter the axle is secured to the wheel and revolves with it.

The determination of the stress distribution in any form of built-up spoked wheel is difficult, either by analysis or experimental means. It has, however, become a matter of some urgency to know accurately what are the maximum stresses in wheels for very heavy duties such, for example, as occur in present-day railway practice.

With the object of showing the general nature of the stresses produced in construction, a simple illustration is chosen of a railway wagon wheel, consisting of a wheel centre of the form shown in the photograph (Fig. 1, *a*), having eight spokes connecting the central hub with the rim, into which an axle is forced and an outer tyre is shrunk on. Into the hub of this model wheel centre, which is constructed of transparent material to a scale of one-twelfth full size, an axle has been forced, but this latter is not seen owing to the vertical stand used for photography, although the stress distribution it causes in the wheel centre is made visible by a beam of circularly polarised light. The photograph shows great stress intensity in the hub and very little in the spokes, except where they join the hub, while at the outer rim the stress, although of small intensity, is of such a nature that the rim experiences a maximum stress at its outer edge opposite to a spoke, and another maximum stress at its inner edge at places midway between adjacent spokes. The chief feature of interest, however, is at the contact surface between the axle and the hub, where the isochromatics show, and the measurements confirm, that the radial pressure P (Fig. 2, *a*) is variable round the axle with maximum values at the spokes, so that this pressure waxes and wanes in the manner shown. In the hub, however, the circumferential tension Q at the axle reaches a minimum value opposite a spoke with only slightly greater values between.

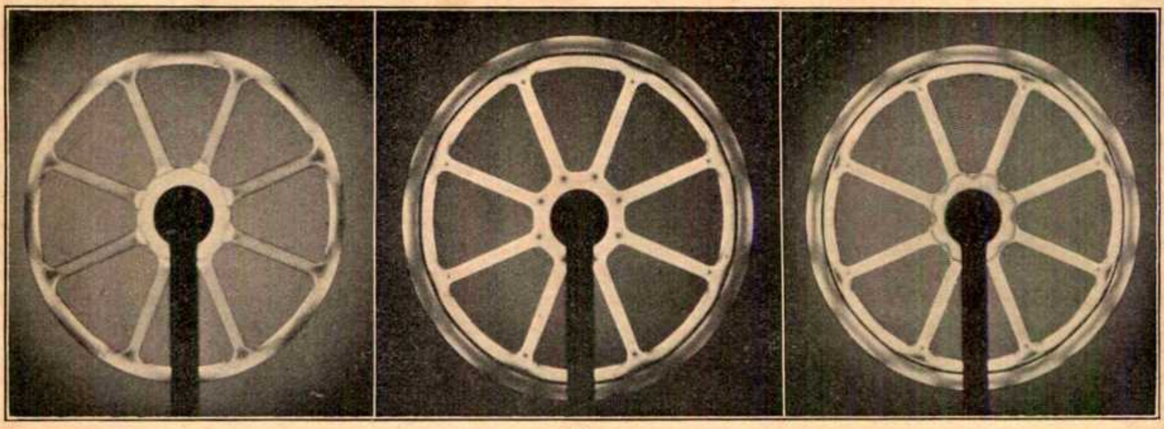

FIG. 1.—*a*: Wheel centre stressed by an axle forced into the hub. *b*: Stress distribution in a tyre and wheel centre before the axle is forced in. *c*: Stress distribution in a completed wheel.

If, instead of forcing an axle into a wheel centre, a tyre is shrunk on first, some interesting features are observed in the wheel centre, due to two separate groups of principal stress differences of zero value, and shown in the photograph (Fig. 1, *b*) by symmetrically placed black dots, one set in the hub and the other in the spokes near their junctions with the rim.

These stress effects, due to the identity in magnitude and sign of the principal stresses, are traced along a spoke in Fig. 2, *b*, where the measured values of the radial stress distribution P, and the corresponding circumferential stress distribution Q, not only confirm the existence of these two groups of stress difference zeros at points A and B, but also show that a third group of low stress intensity exists at points C. The occurrence of this last group is a matter of practical importance, as will appear later.

The principal feature, however, is the high stress intensity in the tyre, which, over a spoke, has a maximum intensity at its outer edge, and a minimum at the inner edge, as shown in Fig. 2, *b*, while midway between the spokes this state of stress is reversed, as we then find a maximum stress at the inner edge with a corresponding minimum at the outer circumference.

In railway work it is the usual practice to force the axle into the wheel centre first, and then shrink on the tyre. When this is accomplished, a stress distribution is found of the kind shown in the photograph (Fig. 1, *c*), in which both the hub and the tyre are highly stressed, while the spokes are still only moderately loaded. As will be noticed here, the two outer groups of stress difference zeros are still present, although in slightly different positions radially. This is seen more clearly in Fig. 2, *c*, where the measured principal stresses *P* and *Q* are shown with reference to a radial plane through the centre of a spoke.

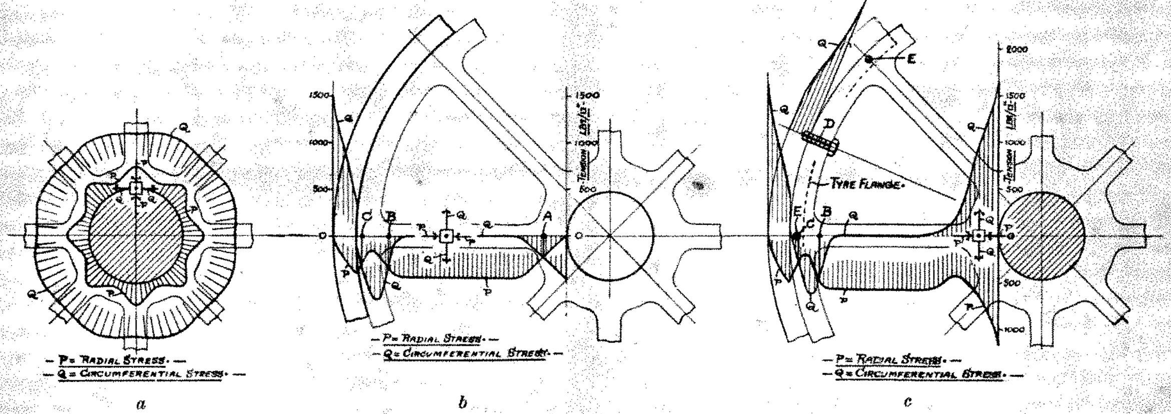

Fig. 2.—*a*: Stress distribution in the hub of a wheel at the axle, when the latter is forced on. *b*: Stress distribution in a wheel, along the line of a spoke, when a tyre is forced on to a wheel centre. *c*: Stress distribution in a wheel when the axle has been forced into the wheel centre and the tyre shrunk on.

These distribution curves also show that the combined effect of both axle and tyre is to increase the radial stress on the axle greatly. In the tyre, increased stress is also apparent, although it remains of the type already described with reference to Figs. 1, *b*, and 2, *b*. This latter distribution is more particularly interesting in its application to much larger wheels, such as the driving wheels of locomotives, where, on account of their size and the necessity of supporting the tyre at short intervals, the number of spokes is much increased, and since, unlike wagon wheels, they are required to exert great tractive force at the rails, it is found necessary to fasten the tyres more securely to the rim of the wheel centre by additional devices, in order to prevent circumferential slipping.

Formerly it was the practice to screw radial studs *D* (Fig. 2, *c*) through the rim of the wheel centre and into the tyre at places midway between the spokes, as indicated here, thereby making holes in the tyre at places where the stress is already intense, and therefore adding to it very greatly, owing partly to the lessened cross-section of the tyre, and also to the effect of the discontinuity, necessitating changes of direction of the tensional stress in passing round the hole so formed. This practice has now been given up in favour of transverse rivets *E* inserted in holes made in the wheel centre rim, very close to the stress difference zeros *C*, and passing through a flange formed on the tyre, which is now constructed to lap over the rim, as indicated by a dotted line in Fig. 2, *c*.

The photoelastic effect shows clearly the advantage of this method of fastening, for the discontinuity now produced by boring a hole at a place near the position of the stress difference zero *C*, where the principal stresses *P* and *Q* are both small, only causes a very moderate increase in both stresses, while no inroad is made into the main cross-section of the tyre. Practical experience has shown that tyres fastened in this way are much stronger and safer than those secured to the wheel centre by the older method, and the advantages of this new form of fastening have secured its very general adoption.

Oxidation by Living Cells.*

By Prof. J. B. S. Haldane.

Until recently our knowledge of the chemistry of respiration stopped abruptly at the boundary of the cell. We knew how the oxygen was carried to it in vertebrate blood, and the carbon dioxide carried away. We also knew that the rate of oxygen consumption by the body as a whole, and by certain organs, was a function of numerous variables, such as temperature, hydrogen ion concentration, nervous stimulation, and so on. A certain number of partially oxidised metabolites, such as β-hydroxybutyric acid, had been isolated. But such quantitative knowledge as existed with regard to the details of oxidation was mainly confined to reactions in which coloured molecules were involved: for example, the reduction of methylene blue to a colourless substance, or the oxidation of *p*-phenylene-diamine to a coloured one.

---

* Substance of lectures delivered at the Royal Institution on Feb. 5, 12, and 19.

The modern period began with the work of Batelli and Stern, and of Bach and Chodat, in Geneva, and since the War the most important centres of research have been the laboratories of Thunberg in Sweden, of Warburg and Wieland in Germany, and of Hopkins in England. This work has led to the recognition of a number of distinct catalysts, each responsible for a different part in the process of respiration. Inorganic catalysts of oxidation may activate the oxidant, the reducer, or both. Thus, Langmuir concluded that when a hot platinum surface catalyses the union of hydrogen and oxygen, a layer of adsorbed O_2 molecules is so activated as to unite with H_2 striking them; but adsorbed H_2 does not unite with bombarding O_2. On the other hand, when the same reaction is catalysed by porcelain, both molecular species must be adsorbed side by side before they react.

We need not, therefore, be surprised to find in the cell catalysts which activate O_2, alongside of activators of reducers such as the lactate ion, and shall be prepared to steer a course between the unitary theories of Warburg [1] and Wieland,[2] who respectively regard the activation of oxygen and of reducers as the fundamental feature of respiration.

When an enzyme catalyses the reaction between two molecular types, one very restricted, the other very general, we describe it as specific for the former. Thus Dixon [3] and Coombs [4] found that xanthine dehydrogenase catalyses the reaction $AH_2 + B = A + BH_2$, where A must be one of a small number of purine bases (it is possible that the same enzyme also activates aldehydes; if so, they are oxidised at about one per cent of the rate of the purines). But B may be oxygen, iodine, nitrate, permanganate, or any of a large number of dyes, such as methylene blue. These latter are perhaps all held on the enzyme surface near the former, but it is difficult to imagine that there is a single molecular grouping responsible for activating all of them. For reaction it is not sufficient that a molecule should be united with the enzyme; it must be activated as well. Thus, uric acid unites with xanthine dehydrogenase at the same spot as xanthine, thus inhibiting its oxidation, but is not oxidised, though another enzyme can accomplish this process.

A large number of dehydrogenases are known which act in a similar manner, each causing the activation of one or more organic substrates. Thus, lactic dehydrogenase, which can be obtained in solution from a number of sources, activates several α-hydroxyacids; succinic dehydrogenase, another enzyme easily obtained in solution, activates succinic and methyl-succinic acids; and so on. The activity of these enzymes is generally measured by the rate at which they catalyse the reduction of methylene blue by their substrates. They usually have a wide range of optimal pH from about 7 to 10, instead of a small range like hydrolytic enzymes, and a fairly constant Q_{10} in the neighbourhood of 2, that is, a critical increment of about 12,000 calories. They are not inhibited by small concentrations of cyanide or sulphide, but are so by the usual enzyme poisons, such as heavy metals and nitrites, and oxidising agents. The formic dehydrogenase of *Bacillus coli* appears to be a copper compound, but there is no evidence that most dehydrogenases contain metals. Quastel [5] and his colleagues have made a very thorough study of the dehydrogenases on the surface of *Bacillus coli*. There are probably at least seven different ones, and possibly many more. In this case they can readily be shown to be concerned in oxygen uptakes. In certain conditions malonic acid inhibits methylene blue reduction by succinic acid, both uniting with the enzyme at the same point; and in high concentrations of both, the rate of reduction of methylene blue depends on the ratio of the two. Cook [6] found that oxygen is reduced at nearly the same rate as methylene blue, and malonic acid inhibits its reduction to about the same extent.

When a dehydrogenase and its specific substrate act directly on O_2 it is reduced to H_2O_2. Some anaerobic bacteria act in this way. Bertho and Glück [7] found that at least 90 per cent of the O_2 consumed by *Bacillus acidophilus* is converted into H_2O_2, which damages the bacteria. But some dehydrogenases when separated will not reduce O_2, and a separate activator is required. We know rather less about the activation of O_2 than of H_2O_2. This latter can be activated by two different enzymes, catalase and peroxidase, and by heat-stable peroxidase-like substances such as cytochrome and hæmatins.

Catalase catalyses the reaction $2H_2O_2 = 2H_2O + O_2$. Zeile and Hellström [8] have shown that it is a derivative of hæmatin with a definite spectrum, and convertible into a hæmochromogen, or into protophyrin. It unites with HCN to give an inactive compound. Under suitable conditions a catalase molecule can destroy more than 10^5 H_2O_2 molecules per second. Peroxidase catalyses the reactions $H_2O_2 + X = H_2O + XO$, or $nH_2O_2 + nX = nH_2O + nXO$, where X may be a large variety of molecules, generally aromatic, but including nitrite and HI. It can be very highly concentrated, and appears to be a coloured iron compound. Its extreme sensitivity to cyanide suggests that it is of a similar nature to catalase.

The oxygen activators (oxygenases or *Atmungsferment*) have been specially studied by Warburg.[1] They unite not only with O_2 but also with CO, for which they have a rather smaller affinity. Like CO-hæmoglobins, the CO-oxygenases are generally sensitive to light. Thus the oxygen uptake of yeast in presence of glucose or alcohol is reduced to about 50 per cent, in a mixture containing ten parts of CO to one of O_2, in the dark. In strong light it returns to almost normal values. By studying the relative efficiencies of different monochromatic lights, Warburg and Negelein [9] found that its spectrum is very similar to that of alkaline hæmatin, and still closer to that of iron-phæophorbide-*b*.

Cook, Haldane, and Mapson [10] worked with *B.*

coli in toluene-saturated buffer solutions. Under these conditions, succinic, lactic, and formic acids each lose two hydrogen atoms and no more. It is thus possible to study reactions much simpler than the complete oxidation of a substance such as glucose. They found that CO and HCN, which in moderate amounts do not prevent oxidations by methylene blue, inhibit oxygen reduction. In both cases the oxidation of lactate is more sensitive than that of formate, while that of succinate is intermediate. Hence there appear to be three oxygenases with specific relative affinities for CO and O_2, like those of the hæmoglobins, and also with different affinities for HCN. Each dehydrogenase is associated with a particular set of oxygenase molecules, for oxygen uptakes in presence of formate and lactate are strictly additive, even when oxygenase activity has been reduced by HCN. If the various dehydrogenases could draw on the same common stock of oxygenase molecules for activated oxygen, this would not be so. This rather rigid organisation is probably exceptional, for oxidations by *B. coli* are largely carried out on its surface, instead of internally, and it does not contain all the three cytochromes. In the absence of toluene, similar but not quite so clear-cut results are obtained.

Cytochrome is the name for a group of metal-porphyrin compounds, the metal being probably iron, which are found in almost all cells, and have been studied by Keilin.[11] When the cell runs short of oxygen, through asphyxia, intense metabolism, or cyanide poisoning, a strong spectrum of cytochrome, resembling that of a mixture of hæmochromogens, appears. If the supply of oxygen becomes adequate, the characteristic bands disappear, being replaced by a fainter spectrum of the alkaline hæmatin type. Cytochrome is not oxygenase, as it does not combine readily with CO or HCN. One of the three components of cytochrome, cytochrome *c*, has been obtained in fairly strong solution. It is a red substance, only slowly oxidised by molecular oxygen, readily by mild oxidising agents. It can be reduced by reducing agents or living tissues, and is an iron-porphyrin compound. Keilin found that the oxygen uptake of a system composed of oxygenase from heart muscle, cytochrome, and cysteine behaves like that of a tissue to cyanide and CO. With this system he was able to show that oxygenase is heat-labile like an enzyme, which cytochrome is not. In plants, a particular type of oxygenase, which Keilin calls catechol oxidase, and the CO compound of which, where investigated, has been found to be insensitive to light, yields H_2O_2 when oxidising catechol and its derivatives, as shown by Onslow.[12]

We can thus give a scheme (Fig. 1) which probably covers most of the oxidation process in the average cell. In anaerobes one or more of the catalysts is absent. Oxygen is activated by oxygenase, which is reduced by cytochrome, and the latter is reduced in turn by dehydrogenases of the common or anaerobic type, that is, those which cannot reduce O_2 directly. This process is occasionally simplified, as in *B. coli*, where cytochrome does not seem to intervene in certain oxidations. Oxygen can also be reduced to H_2O_2, either by catechol oxidase or by an aerobic dehydrogenase. This H_2O_2 is used for further oxidation with peroxidase, or is destroyed by catalase. The latter can act as a safety-valve owing to its low affinity. Whereas peroxidase acts most rapidly in a concentration of H_2O_2 which may be as low as 10^{-6} *M*., catalase has an optimum H_2O_2 concentration of about 0·2 *M*., and at 10^{-6} *M*. is working at only about 0·0004 of its maximum rate. Other substances may act as intermediates. Glutathione appears to remove hydrogen from certain groupings in proteins, the reduced glutathione being later re-oxidised. St. György's[13] hexuronic acid is apparently reduced by dehydrogenases and oxidised by peroxidase. Doubtless many more similar substances will be discovered in future.

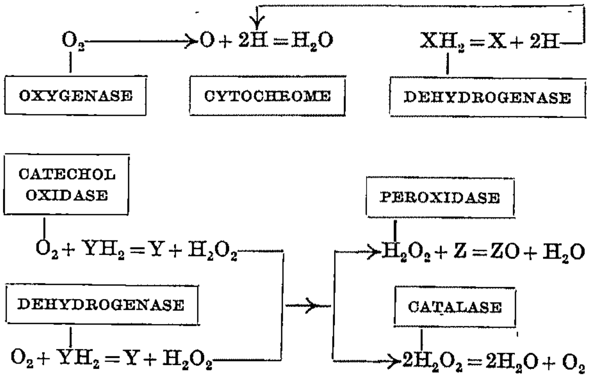

FIG. 1.—The names of the catalysts are given in rectangles, the molecular species activated by each being indicated. The molecule YH_2 is catechol or a derivative in the case of catechol oxidase (Onslow's oxygenase) and is a purine base in the case of xanthine oxidase acting as a reducer of O_2. X and Z may be very varied.

We note the great importance of metal-porphyrin compounds (Table I.). It is fairly clear that their catalytic function is primitive. They have afterwards been modified to act as stores or carriers of oxygen in higher animals. Except in chlorophyll, a magnesium compound, the metal united with the porphyrin is usually, if not always, iron. As oxygenase, catalase, and cytochrome are almost universally distributed, we need not be surprised that hæmoglobin and related pigments such as chlorocruorin have often been independently evolved, a suitable protein being combined with iron-porphyrin residue.

TABLE I.—METAL-PORPHYRIN IN COMPOUNDS FOUND IN CELLS.

1. Catalysts. Chlorophyll *a* and *b*. Oxygenases. Catalases. Probably peroxidases. Cytochrome *a*, *b*, and *c*.
2. Mainly concerned in oxygen storage. *Arenicola* hæmoglobin.
3. Mainly concerned in oxygen carriage. Vertebrate hæmoglobins.
4. Uncertain whether in group 2 or 3. Many invertebrate hæmoglobins. Chlorocruorin. Helicorubin, etc.

We know little as to the immediate source of CO_2. Two obvious processes are available, the dehydrogenation of formic acid, and the decarboxylation of pyruvic acid and related compounds by the enzyme carboxylase according to the equation: $R-CO-COOH=R-COH+CO_2$. The enzymes concerned in both processes have a wide distribution.

Still less is known of how in detail the energy made available in oxidation is passed on, or of how the rate of oxidation is controlled, though both processes are evident enough in the whole organism. The control is largely exercised on the fuel supply. Thus a rise of blood sugar in man causes an increased oxygen consumption. Hormones such as thyroxin are also concerned, but their mode of action is not understood. The energy is not generally liberated directly, but is largely employed in building up compounds of high chemical potential. These may either form new tissue or be available for rapid energy production. Thus the oxidation of sugar or lactic acid in muscle provides energy for the resynthesis of glycogen from lactic acid, and of phosphagen from creatine and phosphate.

If these processes are to be efficient, two conditions must be fulfilled. The energy of oxidation must be made available in quanta somewhat, but not greatly, larger than those required for synthesis; and the molecules undergoing oxidation and synthesis must be united with the same catalyst, which must thus have a double specificity. The significance of the complicated oxidising systems here described will remain obscure until we know what syntheses are correlated with each of them. A beginning of such an analysis has been made by Wurmser.[14] But an indispensable preliminary is a study of the total and free energy changes in the various reactions which are linked. This is still in its very early stages.

But even when we know the stages in the oxidation of different substances, and the use to which the energy thus made available is put, we shall be faced with the problem of regulation. In the living cell the activity of peroxidase or lactic dehydrogenase is doubtless governed by laws as definite as those which govern that of the heart in the living organism, laws which can be stated both in terms of chemistry and of biological function. The question of whether these two types of explanation can be reconciled, or whether one of them is superfluous, will then have to be fought out. However, that day is far distant; meanwhile the biochemist can continue to accumulate knowledge without committing himself on philosophical questions.

Obituary.

Lieut.-Col. Sir Charles Bedford.

THE death of Lieut.-Col. Sir Charles Bedford, which occurred on July 8, terminates a career of scientific activity. Born in 1866, the youngest son of Dr. F. W. Bedford, headmaster of George Heriot's Hospital, Edinburgh, Bedford graduated in science and medicine at the Universty of Edinburgh and entered the Indian Medical Service in 1889. His special aptitude for work of an investigatory character was soon recognised in his appointment by the Punjab Government to be chemical examiner and professor of chemistry at Lahore Medical College. In 1897 he transferred to similar posts in Bengal. Whilst holding these appointments, Bedford rendered valuable assistance to the Indian Excise authorities, particularly in connexion with alcoholic liquors. He became scientific and technical adviser to a committee of investigation into excise questions, and later was appointed director of the Central Excise Laboratory, which was formed on the recommendation of that committee.

It was whilst holding these positions that Bedford performed his most valuable work. Under his direction an extensive investigation was made of all alcoholic liquors produced in or imported into India, their composition and physiological effects, with those of the by-products of manufacture. In 1907 he made a report upon the determination of alcoholic strengths. He submitted new tables intended for use with a glass Sikes's hydrometer in place of those which for upwards of a century had formed the basis of revenue charge. The old tables which were legalised in England in 1816 were compiled for use with a brass hydrometer and covered a range of temperature from 30° to 80° F. For use in warmer climates the tables were extrapolated to 100° F. Strengths determined under these conditions could be regarded as little better than approximations, and Bedford demonstrated that the inevitable errors operated for the most part against the revenue. The new tables were officially adopted in 1908, and remained in use until replaced in 1922 by others calculated from data which formed the basis of the British tables legalised in 1915.

Bedford was also responsible for the methods officially adopted in India for rendering unpotable alcohol intended for commercial and industrial purposes.

After his retirement from the Indian Service, when he was rewarded with a knighthood, Bedford continued to render valuable service in various directions, being a member of numerous committees and occupying advisory positions at home and in connexion with the Dominions. Bedford also found time in the course of a busy life to indulge in considerable literary activity. One of his first publications was a memoir of his father, followed by a history of George Heriot's Hospital. His later works included books on poisoning, enteric fever, and elementary hygiene in India. He received the honorary degree of LL.D. from St. Andrews and Edinburgh, and that of D.C.L. from the University of Oxford.

R. R.

DR. R. C. MACFIE.

ON June 9, in a nursing home in London, Dr. Ronald Campbell Macfie passed quietly from amongst us with whom he had so quietly lived. He was not fond of the limelight, and was intimately known by few, by all of whom, however, he was greatly beloved.

An Aberdonian by birth, he was not in temperament true to type, for he was pre-eminently a man of feeling; yet it was also characteristic of him that he was never without some big problem to ponder over. He graduated in arts and in medicine in the University of Aberdeen, and continued his training in other schools at home and abroad. As locum-tenens at many places and consulting physician in health resorts, he saw a good deal of the world, and he had ever a keen appetite for beauty. With a very high ideal of health of body and health of mind, he lived an ascetic, highly strung life, often with a too strenuous struggle for existence, but, on the whole, rich in high joys and the delights of laborious days.

It was a great encouragement to Dr. Macfie when his poems brought him laureation from his Alma Mater, and he was almost pathetically pleased—two years ago—when he was asked to give the Thomson Lectures in the United Free Church College. These were published under the title "Science Re-discovers God", and they give noble expression to the main trend of his mind. He was spiritually minded, and was convinced that it is the business of science not merely to make the world intelligible, so that a religious interpretation may be more convincing, but to declare a theodicy. His scientific books dealt with heredity and evolution, with vitalism, with health, with the vital value of light, and most successfully of all, we think, with the romance of the body. They were characterised by sparkling lucidity, picturesque phrasing, poetic flashes, and an idealistic setting. His poems, which were his strongest self-expressions, are marked by their combination of music and high thinking. Many of them are little essays in philosophy, and yet at the same time they are melodies.

Of Ronald Campbell Macfie the world did not show itself quite worthy, but he did his day's work cheerfully.

MR. HENRY JAMES WADDINGTON, who died at Bournemouth on June 28 at ninety-one years of age, was well known to microscopic workers both at home and abroad. Many of his preparations, especially those of prawns and crabs, as well as various protozoa, are exhibited in the Natural History Museum, South Kensington. His wonderful manipulative skill at mounting the most delicate protozoa and insects in their natural condition was the admiration of all who came in contact with him. His knowledge of chemistry was an enormous help to him, and his successful preparation of realgar as a mounting medium of high refractive value, as well as his mounts of various diatoms in realgar, are known to many. Mr. Waddington was one of the founders of the Natural Science Society of Bournemouth, and was later presented with the gold medal of the society and elected honorary vice-president.

WE regret to announce the following deaths:

Dr. Francis R. Cross, who was reader in ophthalmology in the University of Bristol and formerly president of the Ophthalmological Society, on July 12, aged eighty-three years.

Prof. Harald Höffding, formerly professor of philosophy in the University of Copenhagen, known for his publications on philosophy and psychology, on July 2, aged eighty-eight years.

Sir Harry R. Reichel, emeritus rector of the University College of North Wales, Bangor, who was principal of the College for forty-three years and known for his work in education, on June 22, aged seventy-four years.

News and Views.

MR. HERBERT MORRISON, Minister of Transport, stated in the House of Commons, on July 24, that the Weir report on the electrification of the railways of Great Britain raises important issues of industrial policy and that the Government will consider its recommendations most carefully. In the opinion of some, an objection to the scheme is that, as the report indicates, the coal consumption will be reduced by 3·8 per cent, or nearly ten million tons a year. It is also true that part of the economy which will be gained will be secured by the reorganisation of the railway men. But it would be foolish to let these two facts prevent us from carrying out a great scheme of industrial improvement. In the making of our country industrially efficient it cannot be wrong to face the new problems and solve them in the same spirit that we solved similar problems in the past. It would be foolish to be frightened because the report deals with big figures. It is significant that the manager of the L.N.E.R. signed the report. The Government is at present discussing the report with the railway companies. The Weir Committee estimated that a return of about 7 per cent could be secured upon the new capital (£261,000,000) involved in electrification. In the present condition of affairs this remuneration would doubtless be welcomed by the companies, but it is doubtful whether they could at present attract the necessary capital without State assistance. At the recent N.U.R. Conference, Mr. C. T. Cramp, the General Secretary of the Union, welcomed electrification on behalf of the employees. He takes it for granted that if the State assists to raise the capital it will assume some kind of control of the scheme. It is probable that a semi-public body of a central board type will have to be made. There is no reason why it should not prove to be as successful as the Central Electricity Board set up by the Electricity Act of 1926.

CONSIDERABLE advances have recently been made in controlling street traffic by means of visual signals. One of the largest of the synchronised systems has now been in operation for a few weeks in Oxford Street, London. It is the first system of this kind in Great Britain and its working will be watched with interest, as before it was started the traffic was very congested. A careful census of the main streets and the cross streets at all times of the day was first taken. From the data thus obtained the whole scheme was worked out. The signal lamps, green, amber, and red, are electrically connected with a ' controller ' fixed on one of the lighting poles and the length of the times the lights are on is easily controlled from it. The speed at which maximum street capacity and efficiency are obtained was roughly determined by the data obtained. It depends on road width, length of blocks, and the nature of the traffic. If the signals are set for a speed higher than the ideal speed, the traffic gets out of step with the system and there is a consequent slowing down. The Oxford Street system was originally set for a speed of thirteen miles per hour, but this has now been increased to a speed of fifteen miles per hour, and it is probable that still higher speeds will be used in the future. The relative density of the cross traffic is an important factor in the calculations. At important crossings such as the one at Oxford Circus, where the volume of the Regent Street traffic is practically the same as the Oxford Street traffic, equal periods of green are given in both directions. At less important crossings the main road has a longer green interval than the cross road. The master controller kiosk is situated on the north side of Oxford Circus and the whole system is controlled from it. There is a private telephone exchange in the kiosk which enables constables on duty to report instantly any defective signal. In the 1½ miles of Oxford Street there are twenty-one groups of traffic signals.

SINCE the War, a very peculiar form of degeneracy has been observable in London sparrows—the breakage of the tail-feathers some time after the moult; this generally occurs close up to their roots, so that at first sight the bird looks as if it had had the quills pulled out, but on close inspection stumps are to be seen, and in some cases the breakage is in the middle of the tail. In any case, it is the outermost feathers that break off nearest the roots, the point of breakage becoming more distant until the central pair are reached, so that the broken tail presents a rounded outline, whereas the undamaged tail is slightly forked. Birds thus affected may be seen in widely separated London districts, and it is curious that they are not otherwise degenerate; their general plumage and condition are average and may even be exceptionally good, while they are often to be seen in company with an intact mate or collecting food for young. Moreover, whatever causes the breakage of the tail-feathers operates quickly on all, as it is rare to see a bird with the tail containing both intact and broken feathers. Before the War, birds showing white feathers here and there were common; then these disappeared for some years, and have only been noticeable again for the last year or two, when, like the broken-tailed birds, they appeared at widely separated points in London: so that whatever cause produces these defects—which are common to both sexes—it operates independently on many isolated individuals.

ALL the four forms of jungle-fowl (*Gallus*) are now to be seen at the London Zoological Gardens—a most instructive exhibit, as the genus is so natural that all recognise the birds immediately as fowls; and yet the species are so distinct that even the hens are as different in plumage as are our four common spotted thrushes—missel, song, redwing, and fieldfare. The cocks are strikingly unlike, as much in voice as in plumage and in details of feathering and head appendages. The most aberrant is the Javan *G. varius*, which has no neck-hackle or wattles, and has indeed been separated as *Creagrus*; yet it agrees with the common *G. gallus* in having the underparts black in the male and brown in the female, and with the Ceylonese *G. lafayetti* in the bold black barring of the wings in the latter sex, in the possession of a dewlap by the male—though this in *lafayetti* is very small—and in the eyes being yellow in both sexes. Between it and the south Indian *G. sonnerati* no special resemblance can be traced; but this agrees with *G. gallus* in having orange-red eyes and in the males assuming ' undress ' neck-feathering after breeding, and with *G. lafayetti* in having the underparts hackled and striated in the male and variegated with black and white in the female, while in these two alone the legs are red in the former and yellow in the latter sex. Yet the male of *G. lafayetti* agrees with that of *G. gallus* in showing much red in the plumage, and in flapping the wings before crowing, unlike the two others; while it may be noted finally that in none of the species except the last-mentioned is the crow at all like that of any tame fowls.

A STATISTICAL report on the third year's operations of the Bureau for Contraceptive Advice, Baltimore, by Prof. Raymond Pearl, is contained in the third report of the Bureau (Baltimore, Maryland, 1931). It is considered that the Bureau has been in operation too short a time to warrant any report on either the relative or the absolute effectiveness of the advice given as to the technique of contraception. In a group of 183 women who came for advice, the average number of pregnancies was 5·5 and the average number of children was 4·7. But their average age was only thirty-one years, and the average duration of marriage was eleven years. These are high reproductive rates which cannot be regarded as helpful to either private or public health. All the women who came to the Bureau were married, and the experience of the Bureau so far demonstrates that there is no validity in the argument sometimes advanced against the giving of contraceptive advice, to the effect that it is chiefly sought by the young as a means of escaping the moral responsibilities of marriage. In this connexion, it may be mentioned that the Ministry of Health has issued a *Memorandum* (153/M.C.W.) stating that local authorities in Great Britain have no general power to establish birth control clinics as such, but that they have under the Public Health Acts power to provide clinics at which medical advice and treatment would be available for women suffering from gynæcological conditions, and that in these advice may be given on contraceptive methods, restricted to married women who attend and in whose cases pregnancy would be detrimental to health.

NEW seismological stations have recently started work in China, Denmark, and Scoresby Sound, Greenland. When the disastrous Kansu earthquake occurred on Dec. 16, 1920, the only seismological station in the whole of China was that of Zikawei, near Shanghai, under the charge of Father Gherzi. Soon after the earthquake, Mr. Wong Wen-hao, the Director of the Geological Survey of China, suggested to the Government that a station should be established in North China, but it was not until September 1929 that permission was given. The place chosen is Chiufeng, about twenty-two miles north-west of Peking (lat. 40° 3′ 55″ N., long. 116° 5′ 46″ E.). The building in which the first instruments (Wiechert horizontal and vertical seismographs) are installed is situated on a granitic hill, 508 feet above the sea. It has been placed under the charge of Mr. S. P. Lee, who has recently issued the first two numbers of the *Seismological Bulletin*, containing the records for about the last three months of 1930. Though they have been somewhat longer at work, a description of the two stations belonging to the Danish Geodetic Institute has recently been published. The station near Copenhagen (opened in November 1926) consists of two caponnieres of the old fortifications, 3¾ miles from the outskirts of the city, both well protected from damp, changes of temperature, and artificial vibrations and provided with Galitzin, Wiechert, Milne-Shaw, and Wood-Anderson seismographs. The second station, containing a set of Galitzin pendulums, is erected at Scoresby Sound, on the east coast of Greenland (lat. 70° 29′ N., long. 21° 57′ W.), and has been at work since January 1928.

IN a recent weekly circular issued by the Ministry of Agriculture, attention is directed to the scheme of exchange of British and Danish agriculturists inaugurated in 1924, under which Danish students are enabled to live and work on farms in Great Britain in order to study English farming practice, and an equal number of young British agriculturists are afforded equivalent opportunities in Denmark. The students are required to pay their own travelling expenses and to undertake regular farm work for a period of from three to twelve months, in return for which free board and lodging is provided but no money paid. Up to the present, only a few students from England have visited Denmark, although the young Danish farmers have made a much fuller use of the exchange scheme. It is, therefore, hoped that more British students will avail themselves of the advantage of this unique opportunity of gaining, at very low cost, an insight into the farming practice of one of the leading agricultural countries. Dairy farming in general, the scientific economic feeding and breeding of dairy cattle, co-operative production, marketing, etc., are the chief branches that may be studied. Those intending to proceed to Denmark for a period of six months or less should arrange to start either early in November or early in May. Agricultural students in England and Wales wishing to take advantage of the scheme should make application through the principal of their college or farm institute (if they have attended such an institution), or through the agricultural officer of the county in which they are resident.

MR. JAMES J. JOICEY, in continuation of a policy pursued by him for many years to the great benefit of the British Museum (Natural History), has presented to the Department of Entomology a further selection consisting of 800 butterflies of very great value and interest from the point of view of the systematic student. These are nearly all 'type' specimens, some of which are unique, that have formed the basis of original scientific work published by Mr. Joicey himself or by other well-known entomologists whose collections have passed into his hands. Two nearly complete skeletons of the reptile *Pachypleurosaurus* from the Alpine Trias have been acquired by the Department of Geology. These animals were shaped like lizards, less than a foot long, and probably lived partly in and partly out of the water. Acquisitions for the Department of Minerals include a small fragment sawn from the 12-ton mass of meteoric iron found in October 1930 near Mbosi, between Lakes Nyasa and Tanganyika, in Tanganyika Territory, presented by Mr. H. V. B. Lloyd Phillips. A fragment of a meteoric stone has been detected amongst the rocks and minerals collected by Mr. Bertram Thomas during his recent expedition across Central Arabia. The Department of Botany has purchased the collections which formed the basis of Dr. Albert Pilát's monographs on Stereaceæ and Aleurodiscaceæ containing 727 specimens of fungi.

THE Imperial Sugar Cane Research Conference, held by the Empire Marketing Board, which concluded on July 24, has recommended the establishment of a chain of four central cane-breeding stations to assist the Empire's sugar industry. Barbados was selected as the site for a cane breeding station in the West Indies. It was recommended that one-third of the expense should be met from Imperial funds and two-thirds by Barbados itself. The three other cane breeding centres would be located in India, Mauritius, and Australia. It was also recommended that a quarantine station should be set up in the West Indies, through which all canes being imported or moved about should pass. Fungus diseases often cannot be detected at once by the most experienced expert, and sometimes they lie dormant in the cane for over a year.

Research on the improvement of agricultural methods, the better interchange of information, and the exchange of workers, are aspects of scientific work which the Conference desires to see extended. It recommended that work on the biological control of insect pests should be continued in the West Indies, and provision should be made for its extension to other Empire countries as occasion may demand.

IN a pamphlet entitled "Mass Production" (Pelican Press, London, 6*d*.) Sir Eric Geddes argues that a protected home market is essential to enable British manufacturers to compete with foreign mass production. He points out that since the War the methods of mass production have developed with great rapidity and its power for the well-being of mankind is enormous, since by cheapening prices it has brought articles of convenience and luxury into the homes of millions who last century could never have dreamed of being able to afford such things. In illustrating the advantages of mass production, Sir Eric Geddes utilises some very interesting diagrams. One of these refers to the drilling of holes in a metal plate, which if done accurately by hand would require a high degree of skill. If performed by a machine, the work no longer depends on the skill of the operative but on the accuracy of his tool, and the cost is seventy-seven times less than that of hand production. In another diagram it is shown that the proportion of labour cost may fall from 50 per cent to 25 per cent when mass production methods are used. To-day the cost of research, experiment, planning, equipment, power, and the maintenance and depreciation of machinery overshadows the cost of productive labour in importance. In the British motor industry, through the partial adoption of mass production methods, workers' earnings have been about doubled since 1914 although prices to the consumer have fallen about one-half.

IT is announced in the *Scotsman* of July 25 that St. Kilda, having been in the hands of the Macleods of Macleod for centuries, has changed owners. Naturalists in general, and ornithologists in particular, will rejoice that its new ownership ensures that the fauna and flora will remain undisturbed, and that the island may be recognised as a natural sanctuary for beasts and birds. Here, if anywhere, the study of the effects of isolation upon species is likely to yield good results. The new owner is the Earl of Dumfries, the eldest son of the Marquess of Bute. Lord Dumfries, born in 1907, is a keen ornithologist who has a first hand knowledge of the birds of southern Europe as well as of Great Britain, and has taken an interest in the arranging of the bird collections in the museum at Rothesay. We understand that all the amenities of St. Kilda will be carefully preserved and safeguarded by the new proprietor, who does not intend to put the island to any commercial use whatsoever.

THE census of Indian mosses (with analytical keys to the genera) published by P. Brühl in the *Records of the Botanical Survey of India*, vol. 13, No. 1, is a large undertaking on which he should be congratulated. The census is at present far-reaching, including Malay to the east and the Caucasus and intervening countries to the west, but as the mosses of these various regions show affinities with those of the various regions of India the wider nature of the census is justified. The addition of keys to the genera and the great advantage gained by the identifications being made possible on vegetative characters will add greatly to the value of the work. Even in Great Britain, it is of enormous advantage to be able to name a moss in the absence of sporogonia, and this must apply much more to bryology in India. Such a census, combined with the keys, should be a big step towards attracting workers in India to bryology; and if students are able to identify a specimen at least so far as to place it in a genus, this should enable them to contribute much to the more detailed knowledge of the mosses and their distribution and, at the same time, to do so without adding unnecessarily to the work of the experts on whom the ultimate identification is almost bound to devolve at the present time.

GENEVA is now the centre not only of the Société des Nations and of the Bureau international de Travail, but also of numerous other societies which have already grouped themselves together in the Fédération des Institutions internationales (semi-officielles et privées) établies à Genève; secretary, Bertram Pickard, 5 Place de la Taconnerie. A list of these will be found in the "Annuaire international de Genève", published by the Centre permanent d'informations internationales, Place des Bergues, 3, Genève. Reference to the League of Nations "Handbook of International Organisations", 1929 edition, shows in the index pages how organisations are developing at other world centres: for example, 14 societies in Vienna, 54 in Brussels, 101 in Paris, 51 in London. Those in Brussels have a possible rallying point in the Palais Mondial, Parc du Cinquantenaire; in Paris the Institut International de Coopération Intellectuelle (2 rue de Montpensier, Palais Royal, Paris, 1er) already organises ententes and liaisons, and its news is published monthly in a *Bulletin de la Coopération Intellectuelle*.

THE late Dr. Bashford Dean, organiser and curator of the Department of Fishes, Recent and Fossil, in the American Museum of Natural History, New York, was remarkably skilled in making drawings of zoological and anatomical preparations. He left many valuable original drawings to illustrate the embryology of three of the lowest existing fishes, and some of his former colleagues and students have now decided to publish these drawings, with explanatory text based so far as is possible on Dean's own notes. The whole will form one quarto volume, entitled "The Bashford Dean Memorial Volume—Archaic Fishes", and will be edited by Dr. Eugene W. Gudger. A preliminary part of the volume, which has already appeared, contains an admirable memorial sketch of Dr. Dean by Prof. William K. Gregory, accompanied by a photogravure portrait, five other portraits which were taken at different periods of his life and activity, and photographs of the tablets to his memory which have been placed in the American Museum of Natural History and the Metropolitan Museum of Art, New York. There is also a complete list of Dr. Dean's writings, including both those on biological subjects and those on armour.

THE Engineering Societies Library of America announces the completion of arrangements for the publication of a series of technical treatises to be known as "Engineering Societies Monographs". The editorial supervision of this series will be in the hands of a committee consisting of Harrison W. Craver, director of the Engineering Societies Library, chairman, and two representatives appointed by each of the following engineering societies: American Mining and Metallurgical Engineers, American Society of Mechanical Engineers, and American Institute of Electrical Engineers. The aim will be to publish important technical manuscripts which have proved too extensive for publication in the periodicals or proceedings of engineering societies or in other journals, and of too specialised a character to justify ordinary commercial publication in book form. The Engineering Societies Library will share in any profits made from publishing the monographs; but the main interest of the societies is service to their members and the public. The monographs will not be a series, in the common use of that term. Physically they will have similarity, but there will be no regular interval in publication or uniformity in price, or relation in subjects. The first volume projected for the series is "Plasticity", by Dr. A. Nadai. It is an adapted and revised translation of Dr. Nadai's well-known treatise in German on this subject.

WE have received from P. J. Kipp and Zonen, of Delft, Holland, a leaflet describing an interesting type of ammeter for measuring very minute alternating currents. It consists of four vacuum thermocouples arranged like the arms of a Wheatstone bridge. A sensitive galvanometer is arranged across one of the diagonals and the terminals are at the extremities of the other: when no current flows, the thermocouples are in equilibrium, the total resistance being twenty-five ohms. An A.C. of one milliampere generates a P.D. of 22·5 microvolts across the terminals of the galvanometer. With a Moll galvanometer, we get a deflection of 500 mm. at a distance of one metre. The four thermocouples are protected against outside disturbances by double-walled metal covers. The instrument can be loaded up to a hundred milliamperes, and can be calibrated with direct current. The Moll galvanometer has a resistance of 50 ohms and a sensitivity of 6×10^{-9} amp. per mm. when the scale is one metre away. The *Zc* galvanometer has a resistance of fifteen ohms and a sensitivity of 10^{-10} amperes.

THE liver treatment of pernicious anæmia is now well established: there are very few cases which do not respond to the administration of fresh liver or a potent extract, and very few which relapse when the treatment is continued regularly. Liver, in fact, has completely changed the outlook for the patient suffering with pernicious anæmia. More recently it has been found that stomach, especially that of the pig, is as effective as liver, and that dried stomach is as potent as fresh. Achlorhydria is an invariable sign in pernicious anæmia. This suggested to Castle that the disease might be due to the failure of the stomach to secrete some principle which formed the anti-anæmic substance from the food, or which was itself a potent source of this substance. Reports from numerous observers indicate that desiccated stomach is as effective as, or even better than, liver in the treatment of pernicious anæmia. The British Drug Houses, Ltd., now issue a potent preparation under the name Gaster Siccata B.D.H. The curative dose is about 30 gm. daily and the maintenance dose 10 gm. The material is almost fat free, odourless and tasteless, and forms a smooth, palatable mixture when suspended in milk.

A LARGE meeting of biologists, including leading representatives of genetics, medicine, and anthropology, was held at the London School of Economics on July 21, to consider the question of the present state of research in human genetics and to explore the possibilities of its immediate development. The lack of facilities for research in a subject so vital to the human race as human genetics was generally deplored, and it was decided to seek ways and means to establish in London a central body of experts, who would organise, develop, and foster sound research in human genetics within the Empire by means of grants obtained from various sources. The following Committee, with power to add to its number, was appointed to take immediate action: Sir Daniel Hall (*chairman*), Sir William Beveridge, Prof. F. A. E. Crew, Sir Walter Morley Fletcher, Prof. R. Ruggles Gates, Prof. J. B. S. Haldane, Prof. Lancelot Hogben, Sir Bernard Mallet, Dr. Redcliffe Salaman, Prof. C. G. Seligman, and Dr. C. C. Hurst (*secretary*).

FOR several years Mr. W. R. Dunlop, of 2 Lynton Road, Hythe, Kent, has been engaged in an objective study of individual mental activity amongst men of business. The field is a new and difficult one and nothing has yet been published. Mr. Dunlop asks for the co-operation of other scientific workers in order that he may investigate the possibilities of a comparative inquiry. He wishes to obtain information which will enable him to compare the working of the mathematical mind with that of the business mind. He wants, especially, information as to how mathematical concepts arise, particularly the extent to which they are definitely suggested by environmental experiences. The opportunity of making a brief systematic analysis of the working of the mathematical mind generally is desired, and Mr. Dunlop asks whether any readers of NATURE would be interested and kind enough to put him in touch with one or more originally-minded mathematicians who would be prepared to co-operate as subjects in a very brief preliminary inquiry.

A SPECIAL exhibition of primitive rafts and canoes, which has been designed to show the successive developments by which these primitive craft have given rise to the built boats of modern Europe, is on view in the entrance hall of the Science Museum, South Kensington, and will remain there until September. These will be illustrated by means of about forty models, and also by sixty illuminated photo-transparencies showing native canoes in actual use. Of special interest is a comparison between the method used by the ancient Egyptians in boat-building and that which is still employed in the almost exactly similar boats of the Ganges; a suggestion is also made of the origin of the Chinese sampan as a development from the catamaran of the Madras coast. Among other primitive types are models illustrating the ways in which the ancient Babylonians, like their modern descendants, used oxhide as a means of transport on the Tigris. A contemporary model of the double-hulled boat built by Sir William Petty in 1663, which has been lent by the Royal Society, provides a very interesting comparison with other double-boats from many parts of the world.

PROF. ENGLEDOW, the chairman of the National Institute of Agricultural Botany, who presided at the annual general meeting of fellows at the Institute's headquarters, Cambridge, on July 24, addressed the audience on the policy of the Institute, and laid particular emphasis on the value of co-operation between national and county organisations and the progress already made in this direction. The Institute with its own seven trial stations has gone far in sifting existing material and stimulating plant breeding, and it is already dealing with thirteen crops and hundreds of varieties. Co-ordinated trials are in progress at 107 centres in 46 counties. This unique undertaking, on a national scale, will provide information of first-rate importance and at the same time ensure that the results are brought home to the farmer. Co-operation of this sort is of inestimable benefit to agriculture; it cannot be too widely known that the Institute's accumulated experience and resources are ever at the service of all who need them, and in particular of county organisers.

THE president of the Board of Education has appointed Sir Richard Glazebrook to be chairman of the Advisory Council of the Science Museum in succession to the late Sir Hugh Bell, Bart.

SIR HUBERT WILKINS, who is contemplating a journey under the ice-cap to the north pole by means of his submarine *Nautilus*, was presented with the gold medal and diploma of the Italian Royal Geographical Society on July 23 on board the *Nautilus*, in recognition of his services to science in connexion with polar research work.

THE Development Commissioners have appointed Prof. G. C. Bourne, Linacre professor of zoology and comparative anatomy in the University of Oxford, to be chairman of their Advisory Committee on Fishery Research in succession to Sir William Hardy, who has resigned. Sir William will remain a member of the Committee, of which he has been chairman for twelve years.

BY an order of the Committee of Privy Council, made after consultation with the Medical Research Council and with the president of the Royal Society, the Right Hon. Lord Dawson of Penn, president of the Royal College of Physicians and physician to the London Hospital, and Prof. Edward Mellanby, professor of pharmacology in the University of Sheffield, have been appointed members of the Medical Research Council in succession to Prof. T. R. Elliott, and Prof. J. B. Leathes, who retire in rotation on Sept. 30.

THE Minister of Health received on July 15 a deputation of members of parliament on the question of the abolition of compulsory vaccination. Mr. Leach said that their object was to secure that compulsory vaccination should be abolished, and they hoped that the Government would introduce, or give facilities for, the necessary legislation. The Minister pointed out that the administration of the Vaccination Acts is now in the hands of the larger local authorities, and the Government would await the experience of the operation of the Acts before contemplating any drastic amendment of the law, to secure which, complicated and highly controversial legislation would be necessary.

A CATALOGUE (No. 17) of some 800 second-hand works on natural history, botany, and horticulture has recently been issued by Mr. J. H. Knowles, 92 Solon Road, S.W.2.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A chief dairy instructor at the East Anglian Institute of Agriculture, Chelmsford—The Clerk of the Essex County Council, Shire Hall, Chelmsford (Aug. 10). A lecturer in mechanical engineering at the Birmingham Central Technical College—The Principal, Central Technical College, Birmingham (Aug. 10). An assistant in agricultural zoology under the Ministry of Agriculture for Northern Ireland—The Secretary, Civil Service Commission, Stormont, Belfast (Aug. 14). A senior demonstrator in anatomy at St. Thomas's Hospital Medical School—The Dean, St. Thomas's Hospital Medical School, S.E.1 (Aug. 15). An assistant lecturer in mechanical engineering at the Hull Municipal Technical College—The Director of Education, Education Offices, Guildhall, Hull (Aug. 15). A physiological chemist at the Cancer Hospital—The Secretary, Cancer Hospital, Fulham Road, S.W.3 (Aug. 22). A demonstrator in zoology in the University of Leeds—The Registrar, University, Leeds (Aug. 24). A research metallurgical analyst under the British Non-Ferrous Metals Research Association —The Director, British Non-Ferrous Metals Research Association, Regnart Buildings, Euston Street, N.W.1 (Aug. 24). A junior assistant in civil engineering at the Queen's University of Belfast—Prof. Hummel, Queen's University, Belfast (Sept. 1). A university reader in pathology at Westminster Hospital Medical School—The Academic Registrar, University of London, S.W.7 (Sept. 18). A Wandsworth scholar at the London School of Hygiene and Tropical Medicine—The Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1 (Sept. 29). An Oxford or Cambridge graduate in physics to teach physics at Clifton College—The Headmaster, Clifton College, Bristol. An assistant pathologist at the Royal Northern Hospital, Holloway—The Secretary, Royal Northern Hospital, Holloway, N.7.

ERRATUM.—In the obituary notice of Major T. F. Chipp in NATURE of July 25, p. 142, par. 2, line 1, for "1919" read "1929".

A Method of Recording Coincidences between Geiger Counters.

RECENTLY the recording of coincidences between Geiger counters has become of considerable interest, and several experimental arrangements have been described for this purpose.[1] A common property of these arrangements is that the resolving power is of nearly the same magnitude as the duration of an impulse from the counter (about 2×10^{-3} sec.). Impulses occurring within a time interval shorter than this are recorded as true coincidences. The method to be described here gives a resolving power about ten times higher; at the same time, it suffers from the disadvantage that the coincidences must be recorded photographically and not by mechanical summation, as is the case with the arrangements mentioned above.

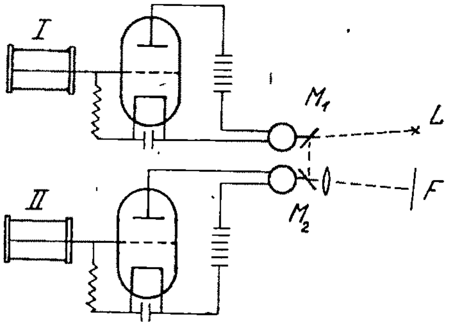

FIG. 1.

Two Geiger counters *I* and *II* (Fig. 1) are connected to the grid of amplifying valves with grid leaks of 5×10^8 to 5×10^9 ohms. The anode current of the valves is sent through moving iron oscillographs of a type similar to that described by Wynn-Williams and Ward.[2] Light from an arc lamp *L* is reflected successively from the plane mirrors M_1 and M_2 of the oscillographs and concentrated by a lens on a slowly moving film *F*. The deflections of M_1 and M_2 are crossed, so that one mirror gives a horizontal deflection, the other a vertical one.

In Fig. 2, *x* represents the direction of the movement of the light spot on the film, and *I* and *II* indicate deflections given by the two mirrors independently. With a natural frequency of 1000 of the oscillograph, the time taken by the light spot to reach full deflection is nearly equal to the duration of the impulse from the counter; the movement of the light spot back to zero deflection is determined by the discharge of the grid capacity over the grid leak, and can be varied at will within certain limits. If a coincidence occurs, the two mirrors commence their movements simultaneously, and the deflection obtained on the film makes an angle of 45° with the direction of *x* (Fig. 2, *a*). If the impulses from the counters occur with a time difference, the deflection appears as a broken line, as indicated in Fig. 2, *b* and *c*, where the time difference is shorter or longer respectively than the duration of the impulse. The position of the kink gives an estimate of the time difference between the impulses. On actual photographs, the smallest time difference which can be detected with certainty is about a tenth of the time taken to reach a full deflection, or about 2×10^{-4} sec. This quantity represents the resolving power of the arrangement. The same value for the resolving power was obtained by counting the number of coincidences when the counters were excited by γ-rays, the coincidences being regarded as accidental. When the same particle (α- or β-particles) was sent through both counters, all coincidences were true (apart from natural effect), so that the time lag in the action of the counter, if it exists, must be identical for the counters used to within 2×10^{-4} sec.

An Investigation of Infra-Red Radiation from an Engine.

A PRELIMINARY investigation of infra-red radiation from a small single cylinder Otto cycle engine delivering power has just been completed.

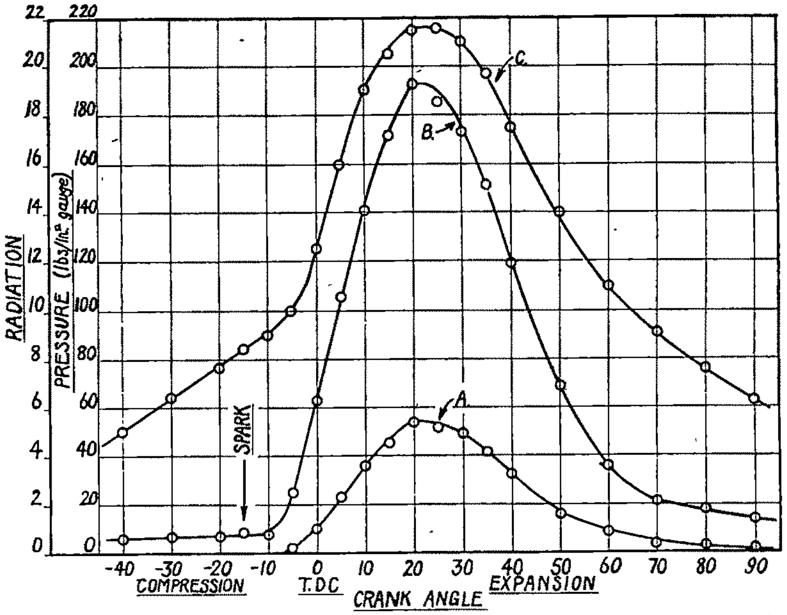

FIG. 1.

The radiation passes through a fluorite window, slightly greater than three millimetres in diameter, and three millimetres thick. Thirty-one positions symmetrically distributed over the combustion chamber are available for the window, and in each a view is obtained through a small depth of charge, in a direction perpendicular to the motion of the flame. By a system of surface silvered mirrors the radiation is brought to a focus on the slit of a stroboscope, which can be adjusted to remain open for any period up to twenty degrees of crank angle, at any point of the cycle. The divergent beam of radiation beyond the stroboscope is reflected from a short focus silvered mirror and focused on a sensitive single junction antimony-bismuth vacuum thermocouple. The e.m.f. generated is measured on a Moll galvanometer with scale at two metres, mounted near the engine on large concrete blocks insulated by heavy rubber, which absorb the engine vibrations at all operating speeds.

The curves submitted (Fig. 1) are plotted on a crank angle base, and show: (*A*) Radiation to 4·4 μ; (*B*) radiation to 10 μ; (*C*) pressure in the combustion space. Curve (*A*) was obtained by placing a piece of plate-glass 4·5 millimetres thick in the path of the rays. The engine was operating without detonation on a commercial petrol (sp.gr. 0·733) at 900 r.p.m., and the radiation was measured through a window two centimetres from the sparking plug, with the stroboscope open for eight degrees.

By using a more sensitive galvanometer the stroboscope opening may be reduced to one degree, with an increase in the significance of the readings. Liquid and gaseous fuels can be used in the engine, and filters will permit measurements to be made over predetermined wave bands. Information on combustion, depth of the reaction zone behind the flame front, and detonation will be sought.

The study of infra-red radiation from an engine, conceived as a promising piece of graduate research, was fortunately considered complementary to an investigation (for the National Advisory Committee for Aeronautics) of combustion in an engine cylinder, proceeding at the Automotive Power Plants Section of the Bureau of Standards; permission to co-operate was very kindly granted by Dr. H. C. Dickinson. The apparatus used for the radiation measurements, and much valuable advice, was furnished by Dr. W. W. Coblentz, of the Bureau, and by Prof. A. H. Pfund, Dr. F. O. Rice, and Dr. D. H. Andrews, of the Johns Hopkins University, where the writer holds a Commonwealth Fund fellowship. SYDNEY STEELE.

Temperature and Humidity Relations of the Cockroach.

IN a recent paper, Bodenheimer[1] has recorded observations on the temperature-preference of various insects. In his apparatus there is a gradient of temperature, and a number of animals which he puts into the apparatus are free to move along the gradient. The temperature at which each animal comes to rest can be read off, and the arithmetic mean of such temperatures is the preferred temperature. He finds that the humidity of the air in which the animals are kept *before* the experiment has an effect on the preferred temperature. For example, *Adesmia clathrata* (tenebrionid beetle), when kept in moist air before the experiment, preferred a temperature of 39·4° C., and when kept in drier air before use, preferred 36·6° C.

In September 1929, I obtained similar results in the course of work on the cockroach, *Blatta orientalis*. The animals were kept in an apparatus similar to the above for four days. In one experiment the air was dry, and in the other it was moist (15·4 mm. v.p., saturated at 18° C.) though not saturated at any but the lowest temperature. At intervals during the four days the temperature-preference was found: the animals were stirred up and then given 20–30 minutes to come to rest before the temperatures were read. The accompanying diagram (Fig. 1) shows how, as time goes on, the insects settle at progressively lower temperatures; each point on the graph represents the average of at least sixteen temperature readings. The change in temperature-preference is much more rapid in dry air than in moist. (I think that the flattening of the dry air curve at about 20° C. is due to the fact that much lower temperatures were not available to the animals, and that the fall in preferred temperature would have continued below 20° C. had the cold end of the gradient been colder. Certainly I have since then had animals which preferred lower temperatures.)

It is well known that insects lose water by evaporation. My experiments show that adult male *B. orientalis* lose water at a rate that is, very roughly, proportional to the drying power of the air, that is, to the difference between the vapour pressure of water in the air and saturation pressure (both in millimetres of mercury) at the same temperature. Such loss may be very rapid. At 30° C. in dry air these animals lose daily an average amount of water equal to about 9 per cent of their original weight, and this continues until they die (four days). With these two observations in mind, I proceeded to investigate the temperature-preference of individual animals, and then—by drying them to constant weight at 100° C.—to find the proportion of water they contained. The investigation is

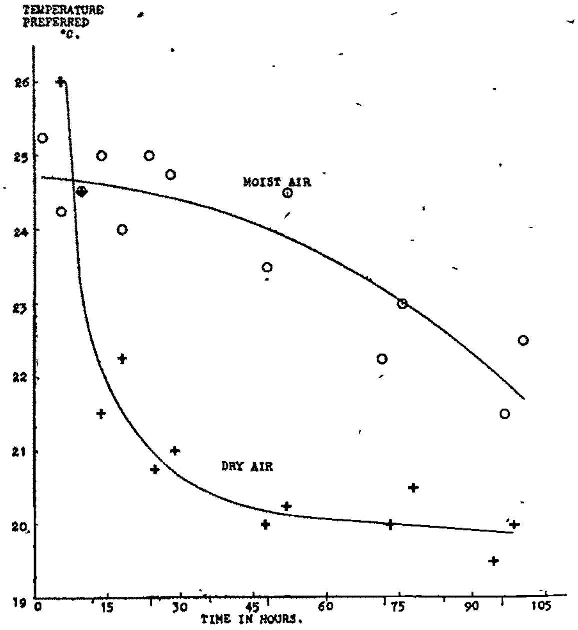

FIG. 1.

Animal.	Percentage of dry weight.	Temperature preferred.
*P*3	25·2	25½
*P*1	28·0	24½
*P*4	28·7	25½
*P*10	29·6	25
*P*2	30·8	19½
*P*6	30·9	18
*P*5	31·3	20½

still in progress and complete results for *B. orientalis* are not yet available, but a few observations which I have made on *Periplaneta americana* show a correlation between dry weight percentage and temperature-preference.

It appears that when the percentage of water has fallen below a certain minimum, the animal seeks a lower temperature than it did previously. Thus, when the animal is kept in air which is not saturated, it loses water at a rate which depends on the drying power of the air. Its percentage of water falls and it then has a lower preferred temperature, with the result that, whether the air is dry or not, it finds itself in air of lower drying power than previously and further loss of water is reduced.

Further work has shown that the food which *Blatta* is given also affects its temperature-preference, and in particular a diet of nothing but sugar solution has a marked effect. A full description of my experiments will be published shortly.

The Pyranoid Structure of Glucuronic Acid and of Theophylline Arabinoside.

In the course of an investigation of the structure of glucuronic acid, we have obtained results which clearly prove that this acid, like the related hexose *d*-glucose, possesses a pyranoid structure. Our starting material was bornyl-*d*-glucuronide (borneol glucuronic acid) isolated as the zinc salt from the urine of humans and dogs receiving small doses of borneol.

Bornyl-*d*-glucuronide has been methylated and the resulting methyl ester of trimethyl bornyl-*d*-glucuronide, which was obtained crystalline, has been converted to the methyl ester of trimethyl methyl-*d*-glucuronide by the use of 1 per cent sulphuric acid in methyl alcohol at 100°. The fully methylated glucuronide, obtained as a liquid mixture of the α- and β-isomerides, has been oxidised with nitric acid ($d = 1{\cdot}42$), using the method first described by Hirst and Purves.[1] The product consisted of a mixture of *d*-dimethoxysuccinic acid and *i-xylo*-trimethoxyglutaric acid. These were purified by distillation as the esters and identified as the crystalline diamides. The final result is therefore similar to that obtained by Hirst [2] in his study of the structure of the normal derivatives of glucose, and a similar conclusion may be drawn in the present case, namely, that the glucuronic acid residue in bornyl glucuronide possesses a ring structure of the pyranoid type.

Challinor, Haworth, and Hirst,[3] from a comparison of the rates of hydrolysis of trimethyl-β-methyl glucuronide and β-methyl glucopyranoside, have deduced a pyranoid structure for the glucuronic acid component of the aldobionic acid from gum arabic. Our direct chemical evidence from material obtained by synthesis in the living animal therefore agrees with that derived from a product of plant origin. In a further series of investigations it has been found possible to methylate *d*-glucurone (the lactone of glucuronic acid) to yield two stereoisomeric crystalline trimethyl glucurones. It seems probable that the second ring system in these compounds is of the furanoid type, but our results do not yet permit us to state that this is so.

Investigations in progress in this laboratory concerning the nature of the sugar of nucleic acids necessitated the synthesis of a purine pentoside. Theophylline arabinoside was selected on account of the stability of its purine residue, and having the material at our disposal the structure of the pentose residue was investigated by the standard methods. The synthesis of theophylline-*l*-arabinoside has been described by Helferich and Kühlewein,[4] and their procedure, using silver theophylline and triacetyl arabinosidyl bromide, has been followed with excellent results.

In view of the method of synthesis adopted, the question of structure possesses a further interest in that a proof of the structure of the pentose residue in the arabinoside establishes by implication the structure of the triacetyl arabinosidyl bromide used in the initial step of the synthesis. No difficulty was experienced in methylating completely the arabinoside and the trimethyl theophylline *l*-arabinoside obtained crystallised readily. The latter was subjected to the action of nitric acid ($d = 1{\cdot}2$) and the main oxidation product of the pentose residue proved to be *d-arabo*-trimethoxyglutaric acid, which was isolated in excellent yield as the dimethyl ester and identified as the crystalline diamide described by Hirst and Robertson.[5] We therefore infer that theophylline arabinoside and triacetyl arabinosidyl bromide are pyranoid compounds. The purine residue of the original arabinoside was isolated as a yellow crystalline compound (m.p. 275°) which reacted and analysed as a nitro-theophylline having the composition $(C_7H_7N_4O_2 . NO_2)_2 . H_2O$. Brunner and Leins[6] have described a nitro-theobromine, but we have been unable to find any reference in the literature to nitro-theophylline. Our compound is presumably 8-nitro-theophylline.

A New Virus Disease of the Tobacco Plant.

In recent years investigators have recognised many virus diseases of the tobacco plant, all, however, producing chlorosis or necrosis of the leaves. I have investigated at Amani a disease of different manifestation, which I believe to be caused by a virus. The characteristic symptom of this disease is leafy outgrowths from the veins on the lower surface of the leaves, sometimes up to a centimetre wide, but usually amounting to no more than a dark green thickening of sections of the veins. Combined with this feature is a stunting of the whole plant and twisting and curling of the leaves. The manifestation of the disease varies greatly according to environmental conditions and the variety of tobacco concerned. I have, however, never observed chlorosis or necrosis in affected plants.

I have successfully transmitted this disease to healthy tobacco plants by grafting diseased scions on to them. I have also produced the disease in healthy plants by transferring to them an undetermined species of whitefly (Aleurodidæ) collected on diseased plants. These experiments carried out under controlled conditions afford evidence which, with my failure to detect a visible parasite, justifies the inclusion of this disease in the virus group.

A condition of the tobacco plant in which the leaves are curled has been reported to occur in most of the tobacco-growing districts of South and East Africa. It is uncertain, however, whether the condition of the plants in any of these regions is due to the same cause as that which I have studied at Amani. Doubtless several forms of leaf-curling occur, attributable to different causes. Workers in South Africa have recognised two types; one, 'curly-leaf', shown by them to be an hereditary abnormality, and a second, 'crinkly-dwarf', of unknown cause.[1] Their description of 'crinkly-dwarf' agrees well with the Amani disease. Roberts[2] attributed a leaf-curl of tobacco in Southern Rhodesia to injury by a capsid bug. Other workers have regarded leaf-curling as a reaction to unfavourable soil conditions. It is possible that the investigation of some of the curly-leaf conditions elsewhere upon the lines which I have followed may demonstrate their identity with the Amani disease.

It is a matter of interest that another whitefly-transmitted virus disease, the leaf-crinkle of cotton, is also characterised by leafy outgrowths from the lower surface of the leaves.[3] H. H. STOREY.

Intensity Anomalies in Rare Gas Spectra.

IN Paschen's analysis of the neon spectrum, and in Meissner's analysis of the argon spectrum, there occur curious irregularities in the d-term sequences, and similar deviations are shown in the spectra of krypton and xenon investigated by Meggers, de Bruin, and Humphreys.

An extension of the system of d-terms in rare gas spectra, to be published elsewhere by one of us (E. R.), has shown intensity irregularities running parallel with the deviations in the term values. The argon spectrum will serve as an example.

The two terms 3302·90 and 1828·40, the classification of which has hitherto been uncertain, are now, due to the observation of several new combinations, definitely classified as $6d_3$ and $8d_3$. These two terms deviate strongly from the Ritz formula. Comparison was then made of the intensities of the lines in the series $2p_{10} - md_5$ and in $2p_{10} - md_3$, which for $m = 5$-7 and 9 are about equally strong, but for $m = 6$ and 8 the combinations are found to be much weaker with d_3 than with d_5. That is to say, intensity anomalies take place for those terms where the greatest deviations from Ritz's formula occur. Exactly the same thing is found in the spectrum of krypton.

In a theoretical interpretation of the origin of these term anomalies a study of the intensity anomalies is certain to play an important part. Therefore one of us (H. S.), engaged in photographic intensity measurements in rare gas spectra, has undertaken quantitative measurements also for the mentioned combinations.

The following intensity ratios indicate the type of deviations which are found:

$$\frac{I(2p_{10} - 5d_3)}{I(2p_{10} - 5d_5)} = \frac{1}{1} \quad \frac{I(2p_{10} - 6d_3)}{I(2p_{10} - 6d_5)} = \frac{1}{6} \quad \frac{I(2p_{10} - 7d_3)}{I(2p_{10} - 7d_5)} = \frac{1}{1}$$

Further measurements are in progress.

We are indebted to Prof. Bohr for his interest in this problem, and one of us (H. S.) has had the privilege of a fellowship from the American-Scandinavian Foundation. EBBE RASMUSSEN.

Effect of Pressure on Raman Spectra.

THE influence of its neighbours on the rotation and vibration states of a molecule in a gas is due partly to the general intermolecular field and partly to actual collisions. From the kinetic theory of gases, it is known that the mean frequency of collisions which a molecule undergoes is given by the ratio P/η of the pressure to the viscosity of the gas. The perturbing influence of collisions on molecular rotation may be expected to be small so long as this frequency is low, but would become considerable when the mean frequency of collision approaches a value comparable to that of molecular rotation. By taking P/η to be equal to the frequency of rotation of the molecule in the one-quantum state, we may obtain an estimate of the pressure at which the distinctness of quantisation of the different rotations would disappear. In this way, the following estimates of pressure in atmospheres at 30° C. are obtained for the different gases: Hydrogen, 450; methane, 48; nitrogen, 29; oxygen, 25; acetylene, 10; carbon dioxide, 5; hydrogen chloride, 128; ammonia, 83; nitric oxide, 25.

These estimates agree remarkably well with actual observations of the pressures above which the discrete lines in the rotational Raman spectrum of the gas disappear and are replaced by a continuous spectrum. I have found that oxygen and nitrogen show the rotational fine structure at a pressure of 20 atm., while only an unresolved band is obtained at a pressure of 30 atm. Houston and Lewis report a similar result for carbon dioxide above 5 atm. pressure.[1] In the other cases, the calculated pressures are uniformly greater than those at which Rasetti and others have actually succeeded in recording the rotational fine structure. It is not improbable that in the case of polar molecules the fine structure might disappear at somewhat lower pressures than those given above, in consequence of the intermolecular fields.

The Slow Combustion of Methane and Ethane.

NOT knowing on what experimental evidence (if any) Dr. Mardles[1] bases his conclusions about the initial 'peroxidation' of methane and ethane to 'methyl hydrogen peroxide' and 'ethyl hydrogen peroxide' respectively during slow combustion in air, may I inquire whether (and, if so, how) he has isolated and identified any such substances so produced? For, as was pointed out in the paper on "The Slow Combustion of Ethane" recently published by Mr. S. G. Hill and me,[2] there has been, so far, no real experimental proof about the initial 'peroxidation' of the hydrocarbons in question in slow combustion; although, as was then shown, the fact that in the case of ethane some slight 'peroxidation' of the intermedially formed acetaldehyde may occur has perhaps confused the issue in some minds and misled some observers.

All I can testify is that, as the outcome of many years' careful experimental study of the combustion of methane and ethane over a very wide range of conditions in my laboratories (both earlier on in Manchester and more recently here in London), no evidence whatever of an initial 'peroxidation' has yet been discovered; on the contrary, the weight of cumulative evidence is so overwhelmingly in favour of an initial 'hydroxylation' that I still regard it as the best interpretation of the known facts.

Moreover, when in due course the details are published of the further experiments recently carried out here (1) by Dr. D. M. Newitt and Mr. A. E. Haffner on the pressure-oxidation of methane and (2) by Mr. R. E. Allum on the kinetics of its slow combustion at atmospheric pressure, I think there will remain but little room for doubt about methyl alcohol being the initial product, unaccompanied by any vestige of a hypothetical 'peroxide'.

If, however, Dr. Mardles can adduce satisfactory experimental proof of his supposed initial formation of 'methyl-hydrogen-peroxide' during the slow combustion of methane, by actually isolating and identifying it among the products, there will be grounds for reconsidering the matter, but otherwise not.

Unusual Lightning.

ON the night of July 12 we witnessed a display of atmospheric electricity which was sufficiently unusual to merit description.

The display was confined to one cloud, low on the horizon in the direction north by west, and apparently at a considerable distance. To one of us, observing from 10.15 P.M. to 10.30 P.M., the phenomena appeared as flame-coloured discharges which recurred in the cloud with considerable regularity at intervals of about a minute and were remarkable for their duration, which was sometimes as great as one second. No thunder was audible.

To the other, observing independently from 10.30 P.M. to 11.30 P.M., the discharges seemed to have their origin in the upper part of the cloud, for each one showed the dark upper edge of the cloud in strong relief: glows of flame-coloured light shone upward and illuminated higher clouds. Sometimes the glow would extend over the whole cloud, sometimes only over a portion of it, and occasionally would start at one end of the cloud and move to the other before being extinguished. The discharges occurred at intervals of one to one and a half minutes, and frequently lasted for a second, in marked contrast to the apparent instantaneity of forked lightning.

Dr. Simpson has suggested that the description tallies well with that of *Flachenblitz*, which appears to be a silent discharge over the surface of a cloud. In his Robert Boyle Lecture (1930) he states that very little is known about this form of discharge and that it is probably due to a kind of St. Elmo's Fire over the whole surface of a cloud.

There is no mention of this form of lightning in the "Encyclopædia Britannica".

Valency and Diamagnetism of Titanium in the Tetrachloride.

TITANIUM (atomic number 22) is known to be paramagnetic. It shows anomaly in that its paramagnetism after decreasing from $1·6 \times 10^{-6}$ at $-170°$ to $1·25 \times 10^{-6}$ at $-80°$ becomes constant. All its compounds so far studied are also known to be paramagnetic; TiO_2, Ti_3O_5, TiS_2, and Ti_2S_3 having values 0·066, 8·1, 0·56, and 0·91 ($\times 10^{-6}$) respectively, for the specific susceptibility (Int. Crit. Tables).

In a recent paper, Weirl[1] has found by electron diffraction that titanium tetrachloride has tetrahedral symmetry with the titanium atom in the centre and the Ti–Cl bonds, being equally and symmetrically directed towards the corners of a tetrahedron. In this case, the titanium central atom has 18 electrons forming a completed group and the four valency electrons symmetrically distributed with respect to the centre, and titanium chloride must be expected to show diamagnetism as contrasted with other compounds of titanium.

An accurate investigation of titanium chloride (a strongly fuming liquid) was made with a sensitive Curie balance, with quartz suspension and retorsion head. The liquid was contained in thin sealed capsules, correction being applied for the latter. The liquid was found to be diamagnetic with a value ($-0·287 \times 10^{-6}$) for the specific susceptibility at 35° C.

This suggests that the paramagnetism of the element titanium is due to the two pairs of valency electrons being in different orbits and giving rise to a resultant paramagnetism, and similarly in the compounds of titanium, the paramagnetism in the compounds is due to the unsymmetrical nature of the valency links. When all the valency links are symmetrically distributed as in titanium tetrachloride, the paramagnetism disappears.

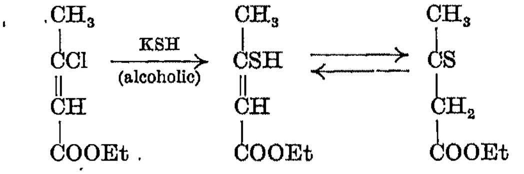
Synthesis of Ethyl Thio-aceto-acetate.

WITH the view of investigating the negative character of the methylene group due to the proximity of : C : S group, Mr. E. K. Mitra, Sir T. N. Palit research scholar, working in my laboratory, has succeeded in effecting the long-looked-for synthesis of ethyl thio-aceto-acetate in the following way:



The mercaptan at the moment of its formation tautomerises as indicated above.

The so-called thio-ester described in the text-books is really diacetoacetic ester sulphide, as is evident from the mode of its preparation and reactions. The new ester behaves exactly like ethylacetoacetate in its reactions towards hydrazines, hydroxylamine, aromatic amines, etc., with the formation of heterocyclic ring compounds. It undergoes Grigniard's, Reformatsky's, and Michael's reactions, resulting in a vast series of interesting compounds. In Knoevenagel's reaction, however, the course taken up is a novel one, giving rise to the formation of thio-aldehydes, hitherto almost unknown in a very good yield. The characteristic behaviour of these true thio-aldehydes and their relationship with ordinary aldehydes are also being closely studied. A detailed account of the investigation will in due course appear in the *Journal of the Indian Chemical Society*.

South Russian Steppe Graves.—The chronological significance of the 'Copper Age' graves in the Pontic steppes is discussed by Prof. V. Gordon Childe in *Man* for July. Both their relative and absolute age are ambiguous. Recently, A. W. Schmidt, of Leningrad, who distinguishes three chronological stages, has assigned the 'Early Kuban phase' to the first half of the third millennium B.C. and the 'Middle Kuban' to 2300–1600 B.C. A. M. Tallgren, on the other hand, would abbreviate the first phase (Maikop and 'royal kurgans') and synchronise it with the Danish Passage-Graves epoch with a date rather after 2000 B.C. The later phase ('catacomb graves') would be parallel to the Long Stone Cists of Denmark, and occupy from 1800 to 1400 B.C. Recent excavations in Denmark and Macedonia have produced decisive evidence. A hammer-headed pin of bone or metal assigned to the Copper Age of the Middle Kuban phase is peculiar to South Russia from the Dnieper to the Caspian. A bone hammer-pin, with all the peculiarities of the South Russian type, was recently found in a passage-grave on Lolland. It belongs to the second of the four phases of the Passage-Grave epoch. Further, an unfinished stone battle-axe of a peculiar form has been discovered in the early Macedonian stratum at Hagios Mamos in Chalcidice. It agrees in smallest detail with one from a grave at Konstantinova near Piatigorsk, associated with grave goods typical of the Middle Kuban phase. Middle Kuban and early Macedonian thus overlap. The early Macedonian is dated about 2000 B.C., which confirms both the third millennium for the Middle Kuban and about 2000–1800 B.C. for the Passage-Grave period in Denmark.

Colorado and Folsom Points.—Flaked points from Colorado, New Mexico, Texas, and Wyoming, which differ in appearance, technique, shape, and quality from those usually found in collections of Indian artefacts, are the subject of a typological study by Dr. E. B. Renaud in the *Proceedings of the Colorado Museum of Natural History* for March 1931. The Colorado points fall into four types, with sub-types in two cases. Broadly, they either have parallel sides tapering to the tip, or are triangular. The base is either square, convex, or concave. The flaking was produced roughly by percussion with a stone, and was finished by pressure with bone or horn. It is on both sides, and some specimens have a marginal retouch. The flaking is parallel and oblique, in some cases extending from edge to edge, in others proceeding from both edges, leaving a central ridge. The flaking of the base was effected as a means of thinning the implement to facilitate hafting. It is also significant, as it leads by stages up to the highly specialised Folsom type. The characteristic Folsom point has as its type station Folsom, New Mexico, but it is also found in Colorado, Wyoming, and elsewhere in New Mexico, presumably being a product of the same culture as occurs at Folsom. Others from these areas approximate to the type. The Folsom point is narrower at the base, which is deeply concave, than at the maximum width of the blade. The characteristic feature, however, is the longitudinal groove. It appears to be the climax, or a late stage, of evolution; but although the Colorado points leading up to it would appear morphologically older, there is no objective proof of their greater antiquity. The Folsom points are said by competent geologists and palæontologists to come from Pleistocene gravels, in which they are associated with a large and extinct species of bison and other fossils. Points from Hugo, Carson, and other sites in the Sandy Rush Creek district, are from 'blow outs', in which, owing to the action of the wind, all objects, irrespective of age, are lowered to a common level.

Bodily Position in Restful Sleep.—It is probably not usually appreciated how much movement takes place during sleep. Investigations at the Mellon Institute, Pittsburgh (" Bodily Positions in Restful Sleep." By Dr. H. M. Johnson. Pp. 24. Pittsburgh: Mellon Institute of Industrial Research, 1931), show that the healthy adult during deep sleep makes some gross change of bodily position on an average every 7–8 minutes. Every sleeper has a repertory of a dozen or more very different poses in which he takes his rest. On any typical night he will make use of all, or nearly all, of this dozen, changing from one to another twenty to sixty times, according to his sensitivity to various kinds of bodily irritation. Among different persons, some have a strong preference for supine positions, others favour prone ones. By means of an ingenious device, photographs were obtained of every change of position assumed by a sleeper during a night, and show an extraordinary range of positions.

Land Birds of Sonora, Mexico.—A study of the birds of Sonora, represented by some 4000 skins, shows that the area, which lies east of the Gulf of California, contains four faunal districts or differentiation areas. The Colorado desert district marches with an extension of the eastern plains area, having many characteristic races. On the other hand, the Tiburon Island district is poorly characterised as regards endemic bird life, although within the most southerly district, Alamos, a great number of resident land birds as well as several littoral species have developed local races. The bird population upon which these districts have stamped local characters is derived from three distinct sources. Most abundant are southern species, which here reach the limit of their range; then follow local representatives of wide-ranging species; and poorest in numbers are birds of northern derivation, also at the extreme of their range. This faunal aggregation forms a strong contrast with that on the other side of the Gulf of California, where, instead of the greater portion of the avifauna, only one species (*Hylocharis xantusii*) possesses southern affinities (A. J. van Rossem in *Trans. San Diego Soc. N.H.*, vol. 6, p. 237, 1931).

Polyembryony in a Braconid Parasite.—*Technical Bulletin* No. 230, March 1931, of the United States Department of Agriculture is devoted to an article by H. L. Parker, who shows that the braconid, *Macrocentrus gifuensis* Ashm., which parasitises the European corn borer in France, undergoes polyembryonic development. While polyembryony is well known in insects, among certain of the Chalcidoidea and Proctotrypoidea, Dr. Parker's studies bring to light the first proved example of its occurrence among Ichneumonoidea. The general details of the process, and the rôle played by the polar bodies, are very similar to what is already known in other groups. There is, however, no proliferation of the host tissue around the embryos to form a definite cyst as in *Encyrtus*. The maximum number of individuals arising from the division of a single egg appears to be eight or ten. Most of the host corn borer larvæ contain several eggs of the parasite owing to the repeated oviposition by the female *Macrocentrus*. As a result, there are usually many more parasite larvæ and embryos present in the host than it can nourish. These supernumerary embryos and larvæ become destroyed during feeding and growth. The *Macrocentrus*, it appears, destroys up to about thirty-six per cent of its hosts, but its efficacy in this respect seems to vary a good deal in different regions of France. The author discusses the most favourable conditions under which consignments of the parasite should be imported and colonised in the United States, as an auxiliary measure in the biological control of the corn borer.

Illumination and Tree Growth.—The *Scientific Proceedings* of the Royal Dublin Society, vol. 19 (N.S.), No. 45 (Oct. 1930), print Part 3 of the investigations on "Photo-electric Measurements of Illumination in Relation to Plant Distribution", by W. R. G. Atkins and Florence A. Stanbury. This part deals with "Certain Spruce, Larch, Oak and Holm Oak Woods". In Part 2 (1929) a description was given of measurements of illumination made with portable galvanometers. The intensities of the illumination in four different types of woodlands were measured, and a study of the floras found at the shaded sites makes it possible to correlate light intensity with plant distribution. The effect of different densities of shade on the ground flora was examined by obtaining data from different woods, such as *Picea excelsa*, pure stand; *Larix europæa*, nearly pure stand; mixed *Quercus ilex*, where undergrowth of *Hedera* prevailed beneath *Quercus robur*; but under *Ilex aquifoliumi* with much reduced light, nothing grew. These investigations should prove of considerable interest, and might not be without their importance to the forester; for example, investigations to show the intensity of the light required for the optimum development of seedlings of the above-mentioned species under the shade of the parent trees.

Marine Algæ from the Pacific.—In a paper entitled "Marine Algæ of the Revillagigido Islands Expedition in 1925" (*Proceedings* of the California Academy of Sciences, fourth series, **19**, 11, Dec. 1930), W. A. Setchell and N. L. Gardner record and describe a large number of Algæ collected by Mr. Herbert L. Mason on the expedition sent out by the California Academy of Sciences. With these are included a few previous records of Algæ from Guadalupe Island, one of the principal islands of the group. The climate is fairly cold, owing to the prevalent north-west winds, and the flora is northern for the latitude and somewhat similar to that of California and lower Oregon, the chilling, at least of the shallower waters, affecting the distribution of the Algæ. One hundred and twenty-five species are recorded, including a few from near the mainland of Mexico; 98 occur on Guadalupe Island and 30 on Clarion Island (the most westerly). Only 5 species are common to both. Two new genera and 29 new species are described. As at present known, 127 species are restricted to Guadalupe and 7 to Clarion Island. The remainder occur also in various parts of the world. An interesting case of distribution is that of *Halothrix lumbricalis*, which occurs locally, always in May only, in western Europe, north-eastern North America, and Guadalupe Island. Good illustrations are given in 15 plates at the end of the paper.

Supernumerary Cell Divisions in Maize.—Last year Mr. George W. Beadle described a variety of maize showing asynapsis, or failure of the chromosomes to pair in meiosis. He now gives an account of a variety in which supernumerary cell divisions occur in connexion with the pollen development (*Mem.* 135, Cornell Univ. Agric. Exp. Sta.). In meiosis the chromosome behaviour is much like that of haploids, that is, the chromosomes do not pair, but are distributed irregularly in both meiotic divisions without splitting. Following these, further mitoses of a similar kind occur, giving rise to as many as 32 cells, some of which frequently have a single chromosome. The pollen of such plants is completely sterile, and very few seeds are produced if the strain is pollinated from the normal. The variety is called *polymitotic*, and the condition is inherited as a simple Mendelian recessive in crosses. It is found to belong to the *Y-Pl* linkage group, and not to be allelomorphic with the gene causing asynapsis. But it is inherited as a sporophytic character, and this can only be accounted for by assuming that the dominant influence of the normal condition continues in the cytoplasm of the young gametophytic cells—cytoplasm which they have received directly from that of the pollen mother cells, in which some stimulus to further cell divisions is present.

Pre-Cambrian Tillite in South-West Africa.—In the *Trans. Geol. Soc. S. Africa*, **34**, pp. 1-17, 1931, Dr. T. W. Gevers describes a tillite from the Pre-Cambrian complex of western Damaraland, which he considers may be even older than the Huronian cobalt tillite of Canada. The tillite occupies a horizon between the quartzite and marble series of the Damara system, the latter being provisionally regarded as equivalent in age to the Swaziland system of South Africa. It has a remarkable resemblance to the Dwyka tillite; is unbedded and unassorted through a thickness of 500-600 ft. and contains numerous faceted boulders and pebbles. The matrix may be argillaceous (now biotite-schist) or arenaceous (now a dense greenish black siliceous rock). Rapid alternations of these are suggestive of varves. The lithological succession as a whole seems to indicate eight or nine major advances of the ice front. In some horizons the quartzites are ripple-marked by currents that flowed from the west. The tillite has already been proved over an area of 5000 square miles, and future exploration is likely to extend this very considerably. The paper includes a tentative classification of the Pre-Cambrian rocks of South-West Africa. The Nama system is regarded as doubtfully Cambrian in accordance with recent fossil discoveries. The Damara system is older than the 'older' gneissose granites, but there are still more ancient rocks: the Pre-Damara gneiss and the Abbabis system.

The Nature of the Aurora.—The *Bulletin* of the American Physical Society published on June 5 contains a note by J. Kaplan on the production of the auroral spectrum in discharge tubes. This has been accomplished by working with air at low pressures (less than 10^{-3} mm. mercury), running the discharge continuously for long periods, and observing it in particular at those periods when after admitting fresh gas to replace that which disappeared during the passage of the current the discharge was again flickering and on the point of being extinguished from lack of gas. Apparently the effect for running a discharge for long periods is to modify the surface of the tube in some way that prevents it destroying the active atomic systems which are responsible for the curious features of the auroral spectrum. From the analogy, Dr. Kaplan draws the conclusion that auroral displays are electrical discharges at low pressures under conditions which are ideal for the production of the nitrogen after-glow. The auroral green line and certain allied lines which arise from atomic oxygen have, of course, been found previously in discharge tubes, but it appears that Dr. Kaplan has succeeded in reproducing the novel features presented by the nitrogen bands in the aurora for the first time.

Spectrum of Carbon Disulphide Flames.—An investigation of the flame of carbon disulphide burning under various conditions is described by Prof. A. Fowler and W. M. Vaidya in the July number of the *Proceedings of the Royal Society*. The band spectra associated with sulphur and many of its compounds are fairly well known, although they are not as yet completely analysed, and it was thought that examination of the light should give information about the chemical processes involved. The ordinary 'hot' flame shows principally the bands of the S_2 molecule. Some of these appear normally not in emission but in absorption, although they can be made to appear in emission by slightly altering the conditions of combustion. Emission bands of the substance SO, which is not known as a chemical individual, appear faintly, whilst if the carbon disulphide is burnt in a chimney, absorption bands of the dioxide (SO_2) also appear. Carbon disulphide can give a colder or 'phosphorescent' flame, and it was already known from the work of H. J. Emeléus that this had a different spectrum. In this, Prof. Fowler has now identified bands of SO and CS, the former being relatively much stronger than in the hot flame. Some preliminary measurements have also been made of a new ultra-violet group of bands, not found in flames, which have been provisionally ascribed to carbonyl sulphide (COS). The spectroscopic evidence gives no evidence for or against the presence of peroxides or carbon monoxide in the flames, but is not completely conclusive.

Rhenium Compounds.—The selenides of rhenium have not previously been described, and considerable uncertainty existed as to the sulphides higher than the disulphide. Briscoe, Robinson, and Stoddart, in the June number of the *Journal of the Chemical Society*, describe experiments which show that the heptasulphide, Re_2S_7, is precipitated incompletely by hydrogen sulphide from ammoniacal solutions of potassium per-rhenate. It is a black amorphous powder, formerly described as ReS_2 or ReS_3. The disulphide, ReS_2, is obtained as a black powder by heating rhenium to redness with excess of sulphur in a Rose crucible under hydrogen sulphide, or by heating the heptasulphide to redness in a vacuum. No evidence was obtained of any sulphide between Re_2S_7 and ReS_2 when the heptasulphide was heated to 250° in an atmosphere of nitrogen. The heptaselenide was obtained in the same manner as the heptasulphide by substituting hydrogen selenide for the sulphide. It is a black powder. On heating in a vacuum at 325°-330° for nine hours it loses selenium, leaving the diselenide stable in air and not attacked except by strong oxidising acids.

Cellulose Lacquers.—The solvents and plasticisers used in the modern manufacture of cellulose lacquers are described in the *Chemical Age* for June 27 by T. H. Durrans. The world's consumption of solvents is estimated at 100,000 tons annually, acetone and the acetates of ethyl, butyl, and amyl being most largely used. Most of the largely used solvents are produced by bacterial fermentation, although there have recently been striking advances in synthetical as well as fermentation processes. The range of commonly used resins and plasticisers is also restricted, the main consumption of plasticisers being confined to triacetin, benzyl alcohol, triphenyl and tricresyl phosphates, and the phthalic esters, whilst ester gum and its derivatives are the only resins universally used. The plasticiser is a most important constituent, the nature and quality of the film depending upon it to a very large extent. The plasticiser is, as Dr. Durrans says, "the master of the cellulose ester film and controls its career throughout its life". A property which is receiving much attention is that of toxicity: unsuspected dangers have been disclosed, as, for example, in the case of glycol chlorhydrin. The same issue of the *Chemical Age* contains other interesting articles on solvents, from which it appears that butyl alcohol and acetone are obtained in America by the fermentation of corn starch, the hydrogen and carbon dioxide evolved being converted into synthetic methyl alcohol, the excess of carbon dioxide being turned into solid, used as a refrigerant under the name of "dry ice". Non-inflammable solvents made on the large scale in England include chlorinated acetylenes (trichlorethylene, perchlorethylene, tetrachlorethane), used for oil extraction, dry-cleaning, degreasing wool, and textile scouring. Artificial resins include the coumarone resins, polymerised from coumarone, a constituent of coal tar.

Astronomical Topics.

New Comet, 1931*b*.—*U.A.I. Circ.* No. 327 announces that a new comet was discovered by Mr. Nagata, and confirmed photographically by Mr. Moore at Mt. Wilson; the following rough position is given:

U.T.	R.A.	N. Decl.
July 17ᵈ 16ʰ 26ᵐ	10ʰ 41ᵐ	9° 48′

The comet is an evening object, too low in the west for convenient observation. There is no information about motion or brightness. The news was transmitted by Mr. van Maanen and Prof. Shapley.

Rapid Current on Jupiter.—The *Observatory* for July contains a report of Mr. B. Peek's paper to the Royal Astronomical Society in which he examined the outbreak in 1929 of rapidly moving dark spots on the south edge of the North Temperate Belt. He noted that there were similar outbreaks in the same zone in 1880, when the late Mr. W. F. Denning found a rotation period of about $9^h\ 48^m$, and in 1891, when Prof. Barnard found a period of $9^h\ 49^m$. The spots of 1929 had a similar short period, though it grew longer towards the end of the year, when the spots were fainter. The period found is even shorter than the average period for the planet's equator ($9^h\ 50^m\ 30^s$) and very much shorter than the average for the temperate zone ($9^h\ 55^m\ 40^s$). Mr. Peek thinks that there may be a permanent rapid current in this region of the planet, and requests that it should be kept under regular observation.

Star Density in Different Galactic Latitudes.—*Mon. Not. Roy. Ast. Soc.* for May contains a paper by Mr. P. J. Melotte which gives the results of star-counts in forty Kapteyn areas photographed at Greenwich with the 26-inch refractor.

The following abridgment of his table gives the logarithm of the number of stars per square degree in the different zones down to the limiting magnitude stated:

	Log. of No. of Stars per Square Degree.		
Limiting Magnitude.	Gal. Lat 0° to 20°.	Gal. Lat. 20° to 40°.	Gal. Lat. 40° to 90°.
11·0	1·34	1·03	0·87
12·5	1·94	1·63	1·32
14·0	2·58	2·11	1·80

In the lower latitudes the logarithms are greater than those of Seares and van Rhijn by about 0·12; the difference tends to disappear in the higher zone. It will be seen that down to mag. 14 the galactic zone is six times as rich as the polar zone. The ratio steadily increases as fainter stars are included.

Textile Research.

THE report of the proceedings of the Imperial Wool Research Conference, 1930, recently published, contains the recommendations of the Conference, with observations on them made by the Imperial Conference, and the papers and addresses given at the Conference, some of which have already been noted in NATURE. A further paper by Mr. A. Frobisher, secretary of the Wool Industries Research Association, entitled "Textile Research on the Continent", which, owing to the pressure of time, was not read at the Conference, is included as an appendix. This paper gives a brief account of the Deutsches Forschunginstitut für Textilindustrie at Dresden, about one-third of the activities of which is devoted to wool problems. At these well-equipped laboratories much fundamental research is carried out under the direction of Dr. Krais, as well as the investigation of purely technological problems, such as the strength and elasticity of yarns, resistance of fabrics to friction, fracture, and folding or creasing. At the Institut für Faserstoffchemie, Berlin-Dahlem, under the direction of Prof. R. Oliver Herzog, pure research on textile fibres is being carried out, the equipment for investigation of the ultimate structure of fibres by X-ray methods being very complete. Excellent facilities are provided for research workers, including visitors from other countries.

Numerous papers on fundamental research on wool improvement have also been published by the Institut für Tierzucht und Vererbungsforschung der Tierartzlichen Hochschule, Hanover, although an important function of this institution is the training of students.

Hitherto there has been no institution in Italy engaged entirely on the solution of problems connected with the woollen and worsted industries, although some wool research is carried out at the textile schools. An institute intended mainly for wool investigations is now being built in Biella and this will be financed entirely by the industry. Wool research in Switzerland is carried out at the Experimental Station, St. Gall, where three research workers are engaged on such problems. In France, industrial research work is largely supervised and financed by the National Office for Scientific, Industrial, and Agricultural Research at Bellevue, near Paris, most of the research work being carried out at the Laboratoire des Services Textiles du Conservatoire National des Arts et Métiers, Paris, and at the laboratory at Roublaix.

In Belgium, collaboration between manufacturers and the research laboratories financed by a national fund for scientific research was ensured in 1929 by the formation of a special Bureau of Industrial and Scientific Relations. Under the agreement, manufacturers may submit special research problems connected with their industries to the laboratories, provided the problems are of general interest. In such cases, the direct expenses of the research are defrayed by the manufacturer.

Textile research has been carried on at the Masaryk Labour Institute in Prague since February 1926, and in 1929 an independent Czechoslovakian Textile Institute was founded to advise the industry on the elimination of waste and improve productive capacity. A Research Institute for the Textile Industry has also existed in Reichenberg for the past eight years and a new building is now being erected. This Institute covers all branches of the textile industry and it has recently constructed a special apparatus, the 'rapid lanometer', for measuring the fineness of wool.

A certain amount of wool research is carried out at Delft by the Dutch Government Information Service for the Textile Industry, and also at the textile schools at Enschede and Tilburg. The Ministry of Agriculture of Hungary has recently established a wool research institute; while a considerable amount of research on wool production is being carried out at the Experimental Station for Animal Husbandry, Boguchwala, ad Rzeszov, Poland, under Dr. Marchlevski. Wool research is also being developed at the Jagellonian University at Cracow, and research on sheep-breeding at the Zootechnical Department of the University of Bukarest.

Wool is included in the ambitious scheme of research for the five-year period drawn up by the Central Research Institute for the Textile Industries (Niti), of the U.S.S.R. The wool section had ten research workers during the first year, a number which is expected to reach fifty-six. The Five Years' Plan includes research on all that is fundamental in providing data for a complete reorganisation of the wool industry on scientific lines.

Textile research is being carried on in Great Britain, notably in the Clothworkers' Departments, University of Leeds. A research scheme was established in 1928 with the aid of a special grant from the Worshipful Company of Clothworkers, and the report for the session 1929–30 contains references to work on the elasticity of wool, the elastic properties of wool in organic liquids, the micelle structure of the wool fibre, and the action of caustic soda and sodium sulphide, which has already been published in NATURE or other scientific journals.

The earlier discovery, resulting from the study of the adsorption of water by wool, that the wool fibre is constructed from long-chain protein molecules arranged lengthways along the fibre, has formed the basis of the work of the past session. In addition, the discovery of a method for measuring the scaliness of different wools and hairs marks the first step towards establishing the milling process on a scientific foundation, the surface scale structure of the fibre being responsible for the felting and shrinking of wool fabrics in the milling process. Other technical investigations have related to the thermal conductivity of textile materials and fabrics, the transmission of water vapour through textile materials and fabrics, and the comparison of wool oils and creams.

Progress in the field of textile physics as a result of X-ray methods has already been noted in NATURE for April 11. The crystallographic picture of the molecular architecture of the wool fibre, although incomplete, has already thrown new light on many typical properties which are of great importance in manufacturing processes. Correct interpretations of conditioning, dyeing, and other adsorptive processes have been facilitated and our ideas of all operations involving the elasticity of the fibre have been clarified. The well-known 'permanent set' of wool fibres is a direct consequence of the action of steam on the stretched β-form of wool (and hair) but not on the unstretched α-form. Results of the X-ray investigation of the wool fibre are related to similar investigations on the structure of natural silk, which finds its counterpart in stretched wool and not in normal wool. Accordingly, silk does not show the long-range elastic properties of wool because it is already in the extended state. The X-ray investigations have also been related to the structure of cellulose, and the structure based on ideas current in Germany is considered unsound. The point is of technical interest in relation to mercerisation.

The Carnegie United Kingdom Trust.

THE seventeenth annual report of the Carnegie United Kingdom Trust gives, by way of introduction to its record of the events of 1930, a short general survey of the five years 1926–1930 and a statement of the main heads of policy which the trustees have decided to pursue during their fourth quinquennium, 1931–1935. Their operations range over a wide field, shared now with the Pilgrim Trust, of charitable enterprise in Great Britain and Ireland. They give preference among charitable objects to such as are of an experimental and national character and to schemes which are likely to become self-supporting within a reasonable time, since it was the founder's desire to provide means for fostering a perpetual succession of pioneer enterprises calculated to meet new needs as they arise. The fairy-godmother, in fact, whilst guaranteeing her protégées a fair chance of showing their quality and merits, is careful to disclaim all responsibility for their future maintenance.

The Trust's income of, roughly, £120,000 a year has been distributed since 1925 mainly in grants under the headings: libraries (47 per cent), playing fields and play-centres (21 per cent), rural development, adult education, and music and drama. In their library development work the trustees have exploited to the utmost the possibilities of co-ordination and co-operation, and this policy led to the establishment in December and January last of two regional schemes of the greatest experimental importance, one in the north of England, based on the library of the Newcastle Literary and Philosophical Society and embracing libraries in the four northern English counties; the other serving Warwickshire, Staffordshire, Worcestershire, Shropshire, and Herefordshire, and based on Birmingham City Library. In each area the trustees are meeting the initial cost of creating the necessary union catalogue. If these schemes, after a short trial period, turn out to be on sound economic and administrative lines, the trustees hope to invite the libraries of two or three other areas to adopt the same policy.

To 'special' libraries, including those of many industrial research and other scientific associations, grants amounting to more than ten thousand pounds were paid last year. These, in return, have made their collections available to the general public on application from the National Central Library. The Association of Special Libraries and Information Bureaux, which has enjoyed the financial support of the Trust during the six years of its existence, has recently decided against a projected amalgamation with the Library Association—a decision involving, the trustees observe, competition and possible overlapping with the university and research section of the Library Association.

The Trust's playing-fields policy, inaugurated in 1927 with an allocation of £200,000 spread over four years, has been carried into effect in collaboration with the National Playing-Fields Association. It has aimed at stimulating and encouraging local effort, and its success may be gauged by the fact that already 356 grants, varying in many cases from only one-tenth to one-sixth of the total cost, have sufficed to enable some 5000 acres to be preserved permanently for the playing of organised games. Apart from this playing-fields programme, the trustees have not during the past year been pursuing any concerted policy for ameliorating the physical welfare of the masses, but they have offered a grant of £30,000 for the erection of a Physical Training College for Men Teachers at Leeds and have helped the National Council of Girls' Clubs to employ two physical training instructresses. The main feature of the college will be a one-year course based on the principle that physical instruction is better given by teachers who also take part in the ordinary work of the school than by specialists with no other qualification and with little, if any, hope of being usefully employed after they reach 40–45 years of age. The Girls' Clubs instructresses conduct short intensive courses in large towns, giving special attention to instruction in the organisation of team games for clubs with limited playing spaces. The experiment is an entirely new one and the results so far are reported to be most encouraging.

A new policy in reference to public museums has recently been decided on by the trustees. Its main feature is a demonstration in public museums, in small towns, designed to show what can be done at a very small cost to make them interesting and educationally valuable. The amount set aside for this purpose is £7000, and will be available solely for re-organisation purposes, in general accordance with the recommendations contained in the report prepared for the Trust by Sir Henry Miers and published in 1928, on "Public Museums of the British Isles". The trustees are also examining the possibility of encouraging the circulation of museum exhibits from urban or county centres to village schools and institutes, and, as a preliminary step, will assist the Museums Association to hold an exhibition of suitable objects, cases, etc.

Appended to the report are useful supplementary notes on the National Central Library and branches, regional library schemes, village halls, and rural community councils.

Atomic Synthesis and Stellar Energy.

By Dr. R. D'E. ATKINSON, Rutgers University.

SOME time ago F. G. Houtermans and the present writer investigated the possibility of synthesis of elements, in stellar interiors, by the wave mechanics process of penetration of nuclei by protons.[1] The theory was not strictly correct, and various modifications have been proposed since, of which the theory of Wilson [2] is perhaps the most important; all theories, however, lead to a probability of proton penetration having the same exponential dependence on both the temperature, T, and the atomic number, Z. The importance of this factor far outweighs that of the multiplicative forefactor which alone is different in the different theories, and it seems therefore desirable to discuss somewhat more fully the consequences of the assumption that any of these theories will give the right order of magnitude for the temperature at which synthesis will occur in large amounts. The effect of the exponential is roughly to make the synthesis probability vary as T^{20}, or some comparable power, and thus even a change of 1000 in the forefactor does not seriously affect T. The investigation is being discussed fully in the *Astrophysical Journal*, but in view of the interest of the subject at present, and also of the comparative unfamiliarity of the line of attack, a short summary may both appeal to a wider audience and prepare the way for the more detailed treatment.

Direct synthesis of helium from hydrogen is clearly a very unsatisfactory process, but we do not need to assume its existence at all; as in the above paper, we assume that helium is produced entirely indirectly, by the spontaneous disintegration of unstable nuclei that must first themselves be formed. In addition to the known radioactive elements, Gamow's theory of nuclear stability [3] now indicates that we may expect a large number of lighter elements to be unstable if they were to be formed, and in fact we rely mainly on these. For example, if above argon the incorporation of electrons, which we clearly must suppose can occur, is somewhat difficult (and the existence of apparently permanent non-radioactive *isobars* seems to show that it can be extremely difficult), nuclei such as Fe^{52}, Ni^{56}, and Zn^{60} may be formed; according to Gamow, the last of these, and quite possibly all three, should be unstable. After emitting one α-particle, they would again collect four protons and two electrons in such order and at such intervals as they could, combine them into a fresh α-particle, and re-emit this one also in due course. At various points in this cycle they would also have to emit a total of just as much energy as would be set free by the direct synthesis of a helium nucleus; this energy can then be used to maintain the star's radiation. This method of evading the well-known difficulty of the 6-body collision as a source of helium obviously opens up important avenues; it is, however, not at all necessary to regard helium as the final product. In fact, since small Z-values favour synthesis, all the helium formed will be rapidly built up again. The energy developed is roughly the same, however, *per proton consumed*, whatever the products.

Since no other theory proposes a lower temperature for an energy source than ours turns out to do, we may take it that stars will at any rate contract until this process becomes operative; they will then be unable to contract further, since even a small contraction will enormously stimulate the energy development and orce them to expand again. Milne's theory seems in this way to be ruled out until such time as the hydrogen supply near the centre has run low.

Rosseland has shown that when there is no great xcess of hydrogen, electrostatic forces will tend to drive it from the centre, and the centre is in any case the only place where it is being consumed. Thus in any star a time will arrive when the disappearance of hydrogen near the centre prevents the generation of nergy there altogether; the star must then condense towards the degenerate state. It is known that the nergy of the white dwarfs may be entirely gravitational if their lifetimes may be supposed to be only of the order of 10^{11} years; in addition to explaining why tars intermediate between white dwarfs and the main sequence seem to be scarce, this theory explains why eavy white dwarfs should be the commonest [4] (the minimum radius is smaller and the square of the mass arger, so that they have very much more gravitational energy available).

So long, however, as hydrogen is present, synthesis hould continue. Since, now, the star's mass remains ractically constant, its energy generation must remain moderately so, and it is easily seen that this involves an approximate constancy of the helium upply, but with an ever-present possibility of adding little to it. This is the fundamental condition for tellar stability, and determines the central temperature. For a star to keep control, it must slowly decrease its central temperature, since the number of helium sources is being added to; thus, after an itial contraction to start the process, stars spend probably the greater part of their lives *expanding*. During ost of their lifetime the expansion is very slow, and the central temperature at any one mass is almost determinate; this accounts for the main sequence.

The actual value for the central temperature cannot, however, be what this simple theory would indicate. If iron is to be synthesised, a temperature of perhaps 200 million degrees would be necessary, and at this temperature all the light elements would be so readily converted to heavier ones that they could not become abundant at all. With a constant helium supply we can use the ordinary equilibrium law of radioactivity theory, namely, that the amounts of the various elements should be directly as their 'average lives'; the fact that we are dealing with synthesis and not disintegration does not affect the validity of the principle. Since the atomic number, Z, affects the synthesis probabilities, that is, the average lives, exponentially, all light elements ought to be very scarce; oxygen is, however, more abundant than anything except hydrogen, and a number of other elements near it are also at least as plentiful as iron.

In fact, it is easily seen that the most abundant element of all in a star must have an average life (until further synthesis) comparable with the past life of the star itself; otherwise some heavier element would be more abundant. If now we assume the central temperature is so low that oxygen is as long-lived as this, we find that it and the lighter elements are nevertheless abundant enough for their synthesis alone to supply enough energy, and that the actual temperature is about 16 million degrees in the sun. This is in agreement with the figure obtained on Eddington's theory for a polytrope of index about three and constitution rather above 50 per cent hydrogen by weight.

At this temperature there is, however, no synthesis of iron, and thus no further supply of helium, and the process will soon exhaust itself. The difficulty may be overcome by an arbitrary assumption, and it has been found possible to make one that accounts at the same time for the permanence and actual position of the main sequence, and for the relative proportions of all the elements in main sequence stars. The assumption is that there is a second synthesis process, which is more probable than the first when $Z>8$ and has a probability that increases somewhat with increasing Z; it must depend about as extremely on the temperature as the other process. Even if this assumption is wrong, it is probably valuable to have the theory investigated in detail; in point of fact, it does at least lead to a number of correct results.

Oxygen will now certainly be the longest lived element, and the products of synthesis will 'pile up' at and near this value of Z. It is, as a matter of fact, desirable to keep them from adding to the iron group which is supplying the helium, for a constant supply is wanted. The iron group itself must, however, be abundant enough to be in 'equilibrium' with the lightest elements, since it must produce as many α-particles per second as there are helium-lithium syntheses. It is found that the situation which will develop involves a marked minimum between the oxygen and the iron maxima and a marked fall after, say, zinc, in very good qualitative agreement with observation.[3] A consideration of Gamow's theory leads us to expect in addition a maximum among and below the lightest rare earths, and possibly one in the lead region; both are found. Practically the entire range of elements thus shows a qualitative agreement with what the theory requires.

The same will be true of any main sequence star; but since the age of the star at a point when it is, say, half hydrogen is much greater for small stars than for large ones, and the density is also larger in small stars, the central temperature must be smaller in them if oxygen is still to have a long enough lifetime. This is satisfactory, for Jeans's modification of Eddington's theory does involve a polytropic index varying systematically with the mass in about the right sort of way to produce this effect. Jeans's modification results from using the theoretical Kramers value for the absorption coefficient, and the main reason why it has not been more generally adopted (by followers of Eddington) than it has is probably that the absolute values obtained by Kramers' theory did not seem to fit the facts. When, however, we adopt Russell's high value for the hydrogen content of stars the discrepancy disappears.

The vast majority of the stars are thus accounted for. The main sequence consists of stars built on the Eddington-Jeans model, with central temperatures fairly sharply defined at any one mass and rising very slowly with the mass, and with a constitution very similar to that actually observed; the central temperature seems to be about 16-20 million degrees in the sun. The white dwarfs consist of a roughly parallel band of stars built nearly on the Milne degenerate model, with central temperatures up to about 3×10^9 degrees; they should have about the same constitution except for a shortage of hydrogen at the centre, and will be fainter for a given mass.

In addition to these two main classes we may account for the low density giants. These have a comparatively low central temperature and can only obtain their energy (*a*) if they have a large amount of free helium or unstable atoms already present, or (*b*) if some very light element can also be unstable. In case (*a*) they will not be able to live very long; but if they are very heavy their total lifetimes will be short anyway, and their life in this state may be a fairly large fraction of the total. The wave mechanics formula used shows that a star of mass 30 suns, if 10 per cent of it were helium and 80 per cent hydrogen, could develop enough energy for an absolute magnitude of -6 even at the density of an *M*5 supergiant, with a central temperature of only 4 million degrees. Such stars will, however, be 'overstable', that is, they will be liable to develop pulsations; these are well known to be a common feature of very massive red stars. If they are not very massive, only a small fraction of their lifetimes can be spent in this state, and they would, in addition, have a very large colour index indeed; we should thus scarcely expect to see any. In case (*b*) a long life would be possible, but as synthesis would now certainly result in an immediate increase in the amount of the unstable element, the stars would have to change their central temperatures over a fairly large range during their lifetimes. The unstable element is assumed to be the isotope Be^8, which exists in very small quantities on the earth and probably has in fact a mass defect (referred to helium as a unit) of very nearly zero. Many beryls contain a large and otherwise unexplained amount of helium, and when the idea of the instability of Be^8 was first proposed, Lord Rayleigh at once pointed out the significance of this fact.[6] The 'Hertzsprung gap' and its prolongation between the Cepheids and the *B* stars may be shown to follow if Be^8 has a long life, and its presence on the earth guarantees this. A long life is also in harmony with the $\mathrm{Be}^8/\mathrm{Be}^9$ ratio and the He/Be ratio.

A number of other observations may readily be fitted into the theory. We may mention in particular the absence of low density stars at medium and small masses, the occurrence of *R* and *N* types among giants but not among dwarfs, the existence of binaries in which the brighter star is the cooler and less dense, and the fact that the brightest stars in clusters are usually all red or all blue.

The arguments that have been urged in support of the 'long time scale' (10^{13}-10^{14} years) may all be met with some plausibility. In particular the well-known theory of Jeans for the eccentricities of binaries, and similar 'kinetic theory' arguments can all be reconciled with the 'short time scale' (10^{11} years) if the galaxy is expanding as fast as the universe in general is; this expansion (for the universe as a whole) seems to be demanded by the general theory of relativity.

It thus appears that as a result of the wave mechanics on one hand, and the general theory of relativity on the other, the universe may have developed its present complexity of stars and of atoms from an initial state consisting of a fairly dense, nearly uniform, nearly stationary mass of cold hydrogen. This comparatively simple beginning constitutes at least a pleasant ornament, if not an actual support, for our theory. It must, however, be admitted that there are still some serious difficulties; those that have been noticed are discussed in the full account which will shortly appear.

Empire Travel for British Students.

FOR the past eight years, parties of Canadian undergraduates, numbering from 50 to 150, and representing most of the universities of Canada, have made a summer tour in Europe under the auspices of the Overseas Education League. The party usually leaves Montreal for Glasgow towards the end of June, and spends about a month in Great Britain, visiting such centres as St. Andrews, Edinburgh, Grasmere, Bangor, Stratford-on-Avon, Oxford, Cambridge, London, and the south coast of England. A further fortnight is then spent in Switzerland, Germany, and France, before the party embarks for Quebec. Last year the continental section of the tour included visits to Geneva, Innsbruck, Oberammergau, Munich, Stuttgart, and Paris.

These tours, of which the great educative value is obvious, represent one activity only of the Overseas Education League. Organised in 1910, on a definitely non-commercial basis, by Major Ney, of Winnipeg, the League was originally designed to foster understanding between Canada and Great Britain. Its scope has gradually widened, and now it "seeks to emphasise the significance attaching to citizenship in th British Commonwealth of Nations, to interpret Britai and France to the two great branches of the Canadia people through a closer educational and cultura association, and to develop a consciousness of the rôl of education as a means to international understanding and amity". It organises summer school of English, French, music, drama, etc., at Oxfor Paris, and other centres; and, in all, some six thousan teachers and undergraduates have taken advantage its arrangements. The Governor-General of Canad is honorary president of the League, and amon other patrons and supporters are the Governo General of the Union of South Africa, Lord Plume the Right Hon. L. C. Amery (honorary vice-presidents the Primate of all Canada (president), and Major F. Ney (vice-president and honorary organiser).

This summer, for the first time, a return visit t Canada of a party of university students from Grea Britain has been arranged under the auspices of th League. A group of about twenty men and wome students of the University of St. Andrews, represent tive of the various years and faculties, will sail for Canada this month in the company of the home-going Canadian undergraduates and various other Canadian parties. Prof. John Read, professor of chemistry in the United College, St. Andrews, will lead the party, and the tour will occupy a period of about five weeks. The visit will be restricted to the eastern provinces, and the party will visit such centres as Quebec, Montreal, Ottawa, Toronto, and Kingston. The return journey from Toronto to Quebec will be made by water via the Thousand Islands. Throughout the tour opportunities will be afforded the members of gaining a first-hand knowledge of the educational institutions, culture, home-life, and resources of the Dominion. The undertaking appears to provide the first instance of an organised visit to a British Dominion by a body of university students from Great Britain, and the evidence afforded by so interesting an experiment should be of particular value.

University and Educational Intelligence.

Edinburgh.—Dr. Charles McNeil, senior physician in the Royal Edinburgh Hospital for Sick Children, has been appointed to the newly founded Edward Clark chair of child life and health.

London.—On the occasion of the centenary meeting of the British Association in September next, the Senate has decided to confer the honorary degree of doctor of science on the president (General the Right Hon. J. C. Smuts), Sir F. Gowland Hopkins, president of the Royal Society, and on the following former presidents of the British Association: the Right Hon. Lord Rutherford of Nelson, Sir Charles Sherrington, and Sir J. J. Thomson.

The governing body of the Lister Institute has appointed Dr. Thomas Fotheringham Macrae to a research studentship in biochemistry.

Dr. Catherine C. Steele has been appointed lecturer in agricultural chemistry and physics at the Horticultural College, Swanley, Kent, and will take up her duties in September next.

Mr. F. N. Mowdawalla has been appointed professor of electrical technology in the Indian Institute of Science, Bangalore, in succession to Prof. J. K. Catterson-Smith.

Applications are invited for the following scholarships at the Huddersfield Technical College:—The Joseph Blamires research scholarship for research in colour chemistry, the value of which is £100 a year with remission of fees, and the British Dyes' research scholarship for research in colour chemistry, value £75 a year with remission of fees. Further particulars and forms of application are obtainable from the Technical College, Huddersfield.

School Life, issued monthly by the United States Office of Education, announces in its January issue that it is undertaking a new task. Not content with publishing notices of the numerous monographs prepared by the staff of the Office of Education, it is to ransack the offices of all government departments, commissions, boards, and other agencies for whatever is likely to be useful to teachers. The first-fruits of this new policy appear in the forms of a full-page advertisement of the Geological Survey's maps—which, by the way, are available to schools at a discount of from 40 to 60 per cent, as compared with the 25 per cent allowed by the Ordnance Survey of Great Britain—the 'Children's Charter' adopted by the White House conference on 'child health and protection', a prison education scheme, and a list of new government publications useful to teachers. The same issue contains articles on unemployment in the teaching profession, instruction classes for the unemployed, the rise of the land-grant colleges and universities, how the schools deal with individual differences, American educational progress in 1930, and a radio transmission station for the joint use of six State agencies, including the university and the departments of public instruction, health, highways, agriculture, and State conservation, of the State of Wisconsin.

Education in India in 1928–29 is reviewed briefly by the Educational Commissioner with the Government of India in a pamphlet recently issued by the Government Publications Branch, Calcutta (price 1*s*. 6*d*.). The number of scholars in institutions of all types in 1929, namely, 12,165,839, shows an increase of 3 per cent in twelve months. During the same period, expenditure on education increased by 5 per cent, to Rs. 27,07,32,253. Expenditure on universities and colleges, providing instruction for 94,257 students, amounted to 13·5 per cent of the total expenditure and showed an increase of 13 per cent over the expenditure of the preceding year. The report suggests doubts as to whether this rapidly increasing expenditure is justifying itself by results. Of the University of Bombay, it is recorded that "the average student does not bother to read his texts but is content to learn by heart second-hand opinions on them, gleaned from cheap bazaar cram-books". The University of the Punjab "is burdening itself, and is encouraging the colleges to burden themselves, with a very large number of students who have little or no chance of completing the course successfully and on whom the expenditure of money intended for higher education is very largely wasted". There is similar wastage also in the University of Rangoon. The number of Indian students in Great Britain is now well over two thousand. Including students at universities on the Continent and in the United States of America, the total number who are abroad in one year is not far short of 2500.

College and school athletics, as related to the educational process, have been dealt with by the Carnegie Foundation for the Advancement of Teaching in a series of publications, beginning in 1927, of which the latest is its Bulletin No. 26 on "Current Developments in American College Sport". In a preface by the president of the Foundation, Mr. Henry Suzzallo, attention is directed to a principle, said to have been long recognised in America but, to the serious detriment of the product of higher education in that country, not always acted upon, namely: "that final responsibility for the effective administration of American college sport belongs not to the alumnus, the down-town business man, or the newspaper writer, but to university or college officers". Many of the changes summarised in the bulletin point to an improvement in this respect. "At numbers of institutions attempts are clearly being made to modify and ultimately to eliminate certain abuses which have their roots in the prevalent commercialisation of American college sport." In several fields of sport, however, in which colleges have been used by professional sports promoters as training grounds for recruits, public aversion to such practices will need to be aroused to a much higher pitch than it has at present reached before their elimination can be looked for. Meanwhile a notable decrease of undergraduate interest in inter-collegiate athletics has taken place in recent years. Complaints by academic teachers that students' interest in the things of the mind is feeble are less frequently heard, and this is attributed to the introduction into intellectual pursuits of the competitive motives which prove so effective in sport.

Birthdays and Research Centres.

Aug. 7, 1864.—Mr. OSWALD H. LATTER, formerly senior science master at Charterhouse.

An investigation of the action of certain chemical substances in stimulating dormant storage organs of plants to activity—for example, ethylene chlorhydrin in the case of *Gladiolus* corms, potassium sulphocyanide in the case of potato tubers—might lead to valuable results.

Aug. 7, 1886.—Prof. P. G. H. BOSWELL, F.R.S., professor of geology in the University of London, Imperial College of Science and Technology, S.W.

To select for special mention from among the various branches of pure geology, oil technology, and mining geology is not easy in a department where students bring problems from many parts of the world and where more than thirty subjects of research are in progress. Detailed observations on the constitution, arrangement, and fossil contents of strata, for example, must proceed; as also the exploration of unknown or little known regions. By these means alone can we fill in the many gaps in the geological record and discover new links in the chain of life.

It is important, however, that the inductive methods of experimental research should be employed side by side with analytical investigations. Hence our aim at the Imperial College is to continue research on such problems as the rôle of water and other mineralisers in the genesis of igneous rocks and metallic ores; the imperfectly understood processes in the formation of clays; and the natural history of sedimentary rocks, both as a problem in pure geology and in its bearing on the origin of petroleum.

Aug. 8, 1857.—Prof. HENRY FAIRFIELD OSBORN, For.Mem.R.S., research professor of zoology in Columbia University and honorary curator of vertebrate palæontology in the American Museum of Natural History.

I began field study of palæontology in the month of August, 1876. I initiated the field explorations from the American Museum in 1891 and became fascinated with the origin and evolution of the proboscideans in 1899, leading to the Fayum Expedition of 1907, in turn to the increasingly intensive study of the evolution of the mastodont, stegodont, and elephantine divisions, especially since the year 1920, when the text of the Titanothere Monograph was completed and sent to the United States Geological Survey for printing. Both stegodonts and elephants have been close travelling companions of man for at least 1,250,000 years, and recently a most interesting discovery has been made that intensive measurement of the ridge plates of the grinding teeth of the proboscideans promises to afford a new and very precise means of dating not only the stegodonts and elephants but also their companion, hunter, and destroyer, prehistoric man.

Aug. 9, 1880.—Prof. M. GREENWOOD, F.R.S., professor of epidemiology and vital statistics in the University of London.

I am at present engaged on the statistical analysis of data of epidemics occurring in groups of mice, with particular reference to the mechanism and quantitative measure of immunisation against bacterial and virus diseases.

Aug. 10, 1865.—Col. Sir CHARLES F. CLOSE, K.B.E., C.B., C.M.G., F.R.S., chairman of the Palestine Exploration Fund; president of the International Population Union; president of the Hants Field Club; formerly president of the Royal Geographical Society.

Three groups of subjects are now of special interest to me. Now that Great Britain has the mandate for Palestine, all possible help should be given to the Palestine Exploration Fund and the British School of Archæology in Jerusalem; and it is most desirable that the headquarters and museum of the Fund should become a real centre and focus of information with regard to the history and archæology of Palestine. Secondly, it is to be hoped that the International Map of the World will make more rapid progress; though much has been done, some countries are lagging behind. In a similar geographical field, a comprehensive English text-book on map projections is badly needed. The admirable 'Germain' is much out of date. Thirdly, all interested in the subject should assist the International Union for the Study of Population Problems and the British National Committee of the Union. The Union is not propagandist and its work is purely scientific.

Aug. 11, 1895.—Dr. C. D. ELLIS, F.R.S., fellow of Trinity College and lecturer in physics in the University of Cambridge.

I am engaged in investigating the β- and γ-ray type of radioactive disintegration. Recent work has shown that there is a close connexion between the energy differences of the α-particle levels in the nucleus and the frequencies of the emitted γ-rays, and it seems a point of importance to ascertain accurately the intensities of the different γ-rays in order to establish correlation in this connexion also with the α-particles.

A further point of great interest which can be conveniently studied by the same type of experiment is the direct coupling between the nucleus and the electronic system which is shown by the so-called 'internal conversion' of the γ-rays.

Societies and Academies.

DUBLIN.

Royal Dublin Society, June 24.—**A. W. Conway**: The influence of the work of Sir William Rowan Hamilton on modern mathematical thought. Hamilton's mathematical work may be divided chronologically into four groups: optics, dynamics, general, and quaternions. His work on optics is dominated by his idea of the 'characteristic function' and his grasp of the fact that this had application either to a wave or to a corpuscular theory of light, representing principles of least (or greatest) time and least (or greatest) action, respectively, on the two theories. His application of the principle of varying action put the whole of dynamics on a new footing, and his methods are to-day freely used.—**Phyllis Clinch**: Cytological studies of potato plants affected with certain virus diseases. A histological and cytological study was made of the mosaic diseases of the potato designated simple and interveinal mosaic, crinkle, streak, and aucuba mosaic. The leaf modifications which underlie the mottling arise in part from underdevelopment of the mesophyll, from a reduction in the number and size of the chloroplasts, and from a paler colour of the chlorophyll. In aucuba mosaic the mottling is almost entirely due to the disintegration of the chloroplasts. Intra-cellular structures of the 'X- body' type occur in all the diseases mentioned, except aucuba mosaic, and in the case of streak only in the early stages. This study tends to emphasise the similarity of all the potato mosaics, except aucuba mosaic, and indicates that streak belongs to the mosaic group.—**W. R. G. Atkins**: Radiation and life. In view of the importance of an adequate degree of illumination for most species of plant and animal life, convenient methods of measuring daylight in various sites on land and in the sea are of considerable utility. Many such measurements have been made by the author and by others using various methods, of which, for general work, the photoelectric cell is, perhaps, the most convenient. Some of the methods used and the results obtained are discussed.

PARIS.

Academy of Sciences, June 8.—**H. Deslandres**: Simple relations between the molecular spectrum and the structure of the molecule. It is shown that apart from any special theory, and working with experimental data only, the molecular infra-red spectrum depends on whole numbers, and may furnish useful indications on the structure of the molecule.—**Georges Claude**: Human respiration in enclosed spaces under reduced pressure.—**Jean Baptiste Senderens**: The comparative hydration of sulphuric acid and of the alkaline bisulphates; its relations with the catalytic activity. The fact that potassium bisulphate treated with air saturated with moisture is hydrated more slowly than sodium bisulphate under the same conditions, is regarded as explaining why sodium bisulphate is a more active catalytic agent towards alcohols than potassium bisulphate.—**Paul Pascal and Mlle. Bernheim**: The study of a mode of transformation of calcium cyanamide into cyanide.—**Edgar Baticle**: The probabilities relating to intermittent phenomena of variable duration.—**Alfred Rosenblatt**: The unicity of partial differential equations of the first order.—**C. E. Winn**: The limits depending on the means of Holder and Cesàro.—**Nikola Obrechkoff**: The summation of Dirichlet's series.—**J. Le Roux**: The invariant expression of the law of gravitation.—**E. Callandreau**: Approximate solutions of the lines of rupture in a pulverent massif.—**Pierre Dive**: The attraction of homogeneous ellipsoids.—**G. Chapas**: The heats of solution of benzoic acid in toluene.—**M. Haissinsky**: The electrochemical and chemical behaviour of polonium in tartaric acid solution. The experimental results are best explained by assuming that the polonium is combined with the tartaric acid in the form of a soluble complex compound, slightly stable and easily hydrolysable.—**Nahmias**: The fluctuation of the path of the α-ray of polonium in different gases.—**Mme. Irène Curie and Marcel Lecoin**: A new gaseous compound of polonium. When polonium, deposited on a nickel needle, is heated in a current of nitrogen, practically the whole of the polonium is deposited in the cooler part of the tube. But if the nitrogen is replaced by a mixture of carbon monoxide and dioxide in equal volumes, about one half of the metal appears to be converted into a gaseous compound, possibly a polonium carbonyl similar to nickel carbonyl.—**Georges Allard**: Electrical moments and molecular constitution.—**W. Swietoslawski**: A boiling point apparatus for examining the purity of liquid chemical individuals.—**L. Lematte, G. Boinot, E. Kahane, and Mme. M. Kahane**: The use of a nitroperchloric mixture for the estimation of silica in vegetable substances. Details of the method, for which both rapidity and accuracy are claimed, are given.—**Sou Phou Ti**: The action of ethylmagnesium bromide on *N*-diethylmonochloracetamide. An unusual transposition takes place in this reaction, the alcohol produced proving to be $(C_2H_5)_2 . N . CH_2 . C(OH) . (C_2H_5)_2$. Suggestions for the probable course of the reaction are given.—**J. Hock**: The synthesis of some derivatives of arylacetic and β-arylpropionic acids.—**Raymond Delaby and Mme. S. Guillot-Allègre**: The α-β-ethylene aldehydes with a linear chain.—**Agostino Puppo**: The storm of July 24, 1930, in the Treviso-Udine district. The damage done by this storm, stated to be the most violent ever observed in Europe, is described. It included destruction of houses, high tension cables, animals, and trees. Human beings were lifted up and carried several hundred metres. The maximum velocity was calculated at 80 metres per second.—**A. Duparque**: The microscopic structure and origin of coking coals and bituminous coals.—**P. Lavialle and P. Jaeger**: The origin of fruit in its relations with pollenisation in *Knautia arvensis*.—**Fernand Moreau and Mlle. C. Morwzi**: Experimental researches on the formation of the perithecium in *Neurospora*.—**C. Charaux and J. Rabaté**: Contribution to the biochemical study of the genus *Salix*. A new glucoside, salipurposide, hydrolysable by emulsin, extracted from the bark of *Salix purpurea*. The new glucoside has the composition $C_{21}H_{22}O_{10}$; on hydrolysis it gives glucose and a substance salipurol, $C_{15}H_{12}O_5$.—**Pierre Gavaudan and Robert Cazalas**: Some teratological phenomena observed during the spermatogenesis of the Characeæ.—**E. Miège**: Strains with polycarpous flowers in a hybrid of *Triticum vulgare*.—**P. Regnier, L. Lespes, and C. Rungs**: The habitat of *Schistocerca gregaria* and the succession of generations in this species.—**A. M. Monnier**: A piezo-electric myograph. Its application to the analysis of the isometric jerk of muscles.—**Jules Amar**: The importance and the signification of the vital capacity.—**Mlle. E. Lebreton, and F. Mocoroa**: The number and nature of the proteolytic ferments of the pancreatic juice. The author concludes from the experiments described that the pancreatic juice as secreted contains, besides prokinase, only the tryptic ferments inactive proteinase and directly active carboxylpeptidase. The ereptic ferments found in the glycerol extracts of pancreas are endocellular and do not normally pass into the juice.—**J. Cayrol and L. Genevois**: The specific inhibition of the alcoholic fermentation of yeast cells without arrest of the respiration, of the Pasteur-Meyerhof reaction, or of growth. A repetition of Lundsgaard's experiment, with the substitution of monobromacetic acid for iodacetic acid, the former being more active and less toxic. Bromacetic acid in the proportion of 14 mgm. per litre completely inhibits fermentation without interfering with respiration, growth, or the Pasteur-Meyerhof reaction.—**Ch. Dhéré**: The fluorescence spectrum of protochlorophyll.—**Mlle. D. Van Stolk, J. Guilbert, H. Penau, and H. Simonnet**: Pure carotene and vitamin A. Full details of the methods of extraction and purification of carotene are given. It is concluded that very pure carotene is capable of maintaining weight equilibrium in the rat and of preventing phenomena of avitaminosis from developing in that animal.—**Cl. Fromageot**: The origin of the energy put at the disposal of micro-organisms in the course of the fermentation of the hexoses.—**Denier la Tour du Pin**: The elective fixation of medicinal ions by the electromagnet. The electromagnet can be used to direct the ions to spots accessible with difficulty; clinical results proving the efficacy of the method are given.—**Georges Blanc and J. Caminopétros**: The virus of exanthematic fever obtained from the blood of patients or from the organism of the tic is filtrable.—**Fréd Vlès, Mlle. Marguerite Prager, and Nissen Bernstein**: The relations between the isoelectric points of human serum and its alexic power.

CAPE TOWN.

Royal Society of South Africa, May 20.—E. L. Halliday: Correlations between the field changes due to lightning and the appearance of the flashes. A preliminary note upon certain results obtained in investigation of the polarity of thunderstorms in the Transvaal. Photographic records of the field changes due to lightning discharges have been combined with visual and photographic observations of the flashes. Of 273 flashes between the base of the cloud and the ground, 257 gave positive field changes and 16 gave negative field changes. Of 173 positive field changes at distances greater than 7 km., 159 were due to flashes to ground. Of 164 discharges within the cloud at distances greater than 7 km., 150 gave negative changes of field.—J. Schonland and C. A. Coppens: Point discharge measurements below thunderstorms. The arrangement used by the authors in Johannesburg and Graaff-Reinet utilises a suitably insulated point and a portable galvanometer. Its simplicity lends itself to the collection of statistical data on the sign and order of magnitude of the fields and field-changes. The arrangement leaves the observer fairly free to note the meteorological features and the distance of the storm.—M. Rindl: The alkaloids of the bark of *Strychnos henningsii*. Two alkaloids have been isolated, a crystalline and an amorphous one. The present paper deals with the methods adopted to isolate the amorphous alkaloid and the endeavours to obtain the base itself, or derivatives of it, in a crystalline form.

SYDNEY.

Royal Society of New South Wales, May 6.—O. U. Vonwiller (presidential address): A generation of electron theory. A review of developments in atomic and light theory since the 'isolation' of the electron, with special reference to the accompanying changes in the philosophic outlook of the physicist from the deterministic view general at the end of the nineteenth century to the uncertainty and probability principles of to-day. It is emphasised that the wave theory of light cannot be regarded as more than a convenient hypothesis in terms of which certain phenomena can be reconciled. Light waves may be considered as a mathematical device which can be used to express the probability of the presence of photons just as de Broglie waves can be used with electrons. The evidence for the objective reality of the waves is no greater in one case than in the other.

The Royal Commission on the Civil Service.*

READERS of NATURE will recall that when the present Government announced its intention of setting up a Royal Commission on the Civil Service, with terms of reference of a seemingly comprehensive character, our satisfaction was qualified by a contemplation of the list of the members of the Commission. Without in any way belittling the attainments and achievements of its sixteen members in their respective avocations, we were compelled to point out that not one was a scientific man or engaged in the application of science to the needs of the community, and that not one was known to have devoted consideration to the more fundamental problems of public administration.

The Commission has now issued a conscientious and painstaking Report, the character of which has confirmed all too well the misgivings which we expressed at the time of its appointment. The Commission shows itself to be dominated almost entirely by the official witnesses, who view with complacency an administrative structure designed by them in relation to the needs of an earlier and more primitive social organisation. It is entitled to credit for having studied and answered—though usually in the negative—the numerous and often constructive criticisms brought to its notice by staff organisations; but it must be rarely that a Royal Commission, confronted with a problem of the magnitude indicated by the terms of reference, can have been so sterile of constructive ideas of its own, and so content to put forward mere glosses on an existing structure, many features of which, so far as it has been modernised, were hurriedly improvised in the immediate post-War years.

Those of us who attribute in no small measure the difficulties with which Great Britain is confronted to failure to give full scope to the scientific and technical expert, had our hopes raised by the inclusion in the terms of reference of the Commission of an instruction to inquire into and report upon the "structure and organisation of the Civil Service". We have never pretended that scientific and technical men and women are not concerned with questions of remuneration, but it has always been our view that remuneration would adjust itself once the true function of the expert had been recognised and his status duly adjusted. The Commissioners, however, following the unfortunate precedent of the Carpenter Committee on the staffs of Government scientific establishments, have carefully avoided consideration of any fundamental questions of structure, including especially those arising out of the employment of specialists—to use a wide term to comprehend professional, scientific, and technical staffs—in the administrative departments of State. The Commissioners' interpretation of the above essential element in their terms of reference is as follows:

---

* Royal Commission on the Civil Service, 1929–31 Report (Cmd. 3909.) Pp. viii + 252. (London: H.M. Stationery Office, 1931.) 3s. 6d. net.

> "It is not our duty to redistribute the functions of Government between Departments, or to re-organise or determine the staff of a Department. But, taking things as they are, it is our duty to determine the most satisfactory general principles to be followed, in regulating recruitment, in fixing terms and conditions of employment, in classifying grades or classes, in distributing functions between grades and classes, and in other like matters."

Two large-scale official inquiries, one dealing with the State scientific services and one dealing with the Civil Service as a whole, have thus seen fit to avoid investigating the wider questions of structure and organisation, beside which matters of staffing, remuneration, and conditions of employment fade into insignificance. There was much in the Report of the Carpenter Committee which could be welcomed as revealing some perception of the need for the development of a State scientific service, even although the problem was not actually visualised in this form, but was approached as a mere simplification of grading and scales of pay so as to ensure uniformity among staffs employed on comparable duties in different departments. Nevertheless, whatever the approach, the Carpenter Report represented progress. The present Royal Commission's Report, however, is little more than a laudation of the *status quo* and an endorsement of Treasury principles and practice based upon conceptions of the scope of public administration current in the latter part of the last century. Without touching on larger questions of administrative policy, however, there were certain proposals with which the Commission deemed itself competent to deal and which were elaborated in the evidence of the Institution of Professional Civil Servants and supported from other points of view by both the British Science Guild and the Association of Scientific Workers.

In the first place, specialist officers are denied a proper share in the formation of policy, a function which resides in the hands of non-technical administrators who alone are entitled to access to the supreme authority represented by the Minister; in the second place, it is most exceptional for the professional or scientific officer, however gifted administratively, to enter the charmed circle of the administrators; and in the third place, there is a complete failure to perceive the fundamental unity which underlies the employment of technical experts by the State, a type of recognition which in other walks of life—even on the administrative side of the Civil Service—has done much to promote esprit de corps, the pre-requisite of administrative efficiency.

There can be no doubt that, in the interests of efficiency, the technical hierarchies should be accorded a status equal to that of the administrative hierarchies, and that, in particular, the chief technical officer in a department should rank on terms of practical equality with the administrative head of the department. When policy is in course of formation or when larger decisions are being taken, the chief technical adviser should be permitted to play as prominent a part as the chief administrative adviser of the Minister, and the board system in one form or another seems peculiarly suitable for securing this result. Under the present system it frequently happens that the technical staff prepare a report and guide the hands of the administrators up to a certain point and then hear no more about the Minister's views until perhaps there is a public pronouncement on the platform or in parliament.

The Commissioners state that they heard no evidence to justify the view that at the present time specialists are disregarded. This statement is apparently based upon the fact that a long series of permanent secretaries expressed complacent satisfaction with the present system. If the Commissioners had heard first-hand information on the point, from professional and scientific heads of departments, we have little doubt that they would then have been satisfied that there is a case for a reform of the present system. They have been misinformed when they assert that "there is no real danger that their (specialist) advice would not be placed before the Minister or official on whom falls the responsibility for the final decision on the issue under consideration".

Nevertheless, the Commissioners are constrained to admit that there may still exist among specialists a feeling that their advice is not always sought and considered, and the pious remedy proposed is that

> "those in positions of administrative responsibility should take special precautions to ensure not merely that specialists are properly consulted and that full consideration is given to their views, but that they are given no ground for feeling that their value is not appreciated. It is important

> that specialists as well as other officers whose duty it is to give advice should be made aware of the decision taken by the responsible authority."

It is precisely because these things do not happen as a matter of course under the present system that there is an urgent need for according the technical advisers a more assured status and a more definite right to assert their points of view in the presence of those who have to take the ultimate decision.

Accepting without qualification the official Treasury evidence, the Commissioners state that they have received no evidence indicating that, when an appointment to the permanent headship of a department is under consideration, regard is not and will not be had to the claims of officers other than those serving in an administrative capacity, and in support of this statement they mention that two of the present permanent heads of departments began their careers on the specialist side of the Service. The Commissioners' findings on this important point are rather discounted by a passage in the chapter of the Report devoted to the Post Office, in which, when discussing the position and remuneration of the engineer-in-chief, they state that they would

> "have expected that over a period of years some technical officers would have been found to possess qualities rendering desirable their transfer to the administrative side. We were told, however, that no officer from the technical side had ever been promoted to an administrative post in the department."

We may remark in passing that entry into the administrative class may be obtained by those whose specialisation at the universities has not been in literary subjects, through the medium of the open competition for posts in the administrative class. This fact is apparently not generally known, and we propose to return to the subject in a subsequent issue. However, we would urge that the very fact that the administrative faculty in its highest sense is rare, renders it essential that the field from which administrators are drawn should be as wide as possible, and just as it is now repugnant that qualified persons should be denied public appointments on political, social, or religious grounds, so it should be equally accepted that no man should be virtually debarred from administrative preferment merely because he possesses precise and ordered knowledge of a particular branch of science.

Finally, there was the possibility of approach to the problem of raising the status of the technical expert by simplifying the extraordinarily heterogeneous collection of grades and salaries which obtains in the professional and technical services. As we have indicated, the Carpenter Committee made important recommendations, which are endorsed by the Commissioners, to secure greater uniformity in the scientific departments. According to the evidence submitted by the Institution of Professional Civil Servants, there are actually more than five hundred separate grades in the professional and technical services, revealing minute salary differences one from another, ostensibly based upon a fine weighing up by the 'establishment' experts (all of whom are administrators) of the relative values of the services performed by these officers. One would have thought that a *prima facie* case for rationalisation would have been afforded by the history of the non-technical services, which in the past revealed the same multiplicity of grading, most of which has disappeared as a result of a process of 'reorganisation'. A similar problem has confronted the Canadian technical service, and the recent report of the Canadian Royal Commission has recommended the replacement of 203 separate grades by seven simplified hierarchies.

This issue of simplification is something more than a desire for symmetry, for the acceptance of the principle that the grading and remuneration of professional and technical officers in different occupations should be unified would pave the way to that public recognition of the technical services of the State, which is a necessary precursor to the granting to the staff concerned of a higher status in the official hierarchy. The Commissioners state that it was not possible for them to review in detail the organisation of the various specialist classes outside the terms of reference of the Carpenter Committee, nor, as we understand, did the Commissioners make any detailed investigation of the actual working of the professional and technical departments. The fact that they were without any real first-hand acquaintance with the specialist services did not prevent the Commissioners from pronouncing quite definitely against the various proposals to which we have referred for enhancing the status of the expert or from stating that there is no justification for an improvement in remuneration except in the case of some of the highest technical posts.

The constructive proposals put to the Commission were rejected out of hand, with the qualification that the Commission admitted the extraordinary anomaly of paying between £1600 and £1700 a year to the engineer-in-chief at the Post Office, responsible for the technical side of the conduct of the State's telegraph and telephone enterprises, and for the control of an army of workmen and of professional and technical officers, whereas the secretary of the Post Office receives £3000 a year. The Commission recommends that the engineer-in-chief should receive £2500. This, coupled with a suggestion that the secretary of the Department of Scientific and Industrial Research, who now receives £2200, should receive £2500, and that in the highest professional posts adjustment of salaries is required, represents substantially the whole of the Commissioners' reactions to the suggestion that the employment of specialist officers by the State presents a special problem that requires reconsideration in the light of modern conditions.

When confronted by the problem of the Post Office, the Commissioners not unnaturally quailed, and took refuge in a suggestion that the importance of the issues raised by a State trading enterprise pointed to the need for a special committee or commission to inquire into Post Office organisation. It does not appear to have occurred to the Commissioners that *a fortiori* there was an overwhelming case for a special committee or commission to inquire into the even more difficult problem of the professional, scientific, and technical services, to which they admit they gave no detailed consideration.

While we have no hesitation in describing the Report as a disaster from the point of view of the welfare of the community, it would not be just to place the whole of the blame upon the Commissioners, many of whom, in view of their public position, must be regarded as being in close touch with informed public opinion. The failure to appreciate the significance of the expert in public administration is but a symptom of the more widespread failure to realise that the ills which now beset civilised communities can only be solved by scientific method and the utilisation of scientific discovery. Our task must continue to be the creation of an informed public opinion which will instinctively exhibit indignation when important public questions involving scientific considerations are discussed without the assistance of experts, and will insist that on all public inquiries there should be a due representation of experts familiar with the subject-matter of such inquiries.

Magical Belief and Practice.

(1) *Amulets and Superstitions: the Original Texts with Translations and Descriptions of a Long Series of Egyptian, Sumerian, Assyrian, Hebrew, Christian, Gnostic, and Muslim Amulets and Talismans and Magical Figures, with Chapters on the Evil Eye, the Origin of the Amulet, the Pentagon, the Swăstika, the Cross (Pagan and Christian), the Properties of Stones, Rings, Divination, Numbers, the Kabbâlâh, Ancient Astrology, etc.* By Sir E. A. Wallis Budge. Pp. xxxix + 543 + 22 plates. (London: Oxford University Press, 1930.) 30*s.* net.

(2) *Le livre de recettes d'un dabtara abyssin.* Par Marcel Griaule. (Université de Paris: Travaux et mémoires de l'Institut d'Ethnologie, tome 12.) Pp. xi + 180. (Paris: Institut d'Ethnologie, 1930.) 70 francs.

(1) BELIEF in the power of the amulet is one of the most interesting phenomena in the history of religious belief. In close alliance with 'magic' it appears as one of the earliest forms of man's belief in the forces which he believes to lie behind the perceptions of his senses: as the mascot it serves to testify to the last act of faith of a disintegrated religion. How closely the extremes of the scale approach one another appears in some instructions on the choice of amulets published a few years ago, in which the writer argued the possibility that there might be something in it on the analogy of wireless telegraphy. No anthropologist in search of *mana* in religious belief could desire a more illuminating example; but after saying this we hesitate to suggest that Sir Wallis Budge himself is not guiltless of flirting with the idea that "there may be something in it".

In his study of the amulet and allied beliefs, Sir Wallis Budge has confined himself to ancient Egypt and Babylonia, the later Kabbalists, the Gnostics, pagan and Christian, and the astrologers. Virtually his field is the ancient Mediterranean area. Within these limits he has covered the ground with no little thoroughness. In fact there is scarcely any aspect of magical belief and practice on which he has not touched. In addition, he has added to the evidence from his experience among makers of horoscopes, casters of nativities, diviners, crystal-gazers, palmists, and fortune-tellers of all kinds whom he has met while engaged on official missions in Egypt, the Sudan, and Mesopotamia—a fruitful field as all will agree who know the superstitious reverence and profound belief with which such classes are regarded by the populace in these countries.

"The use of amulets", says the author, "dates from the time when animism or magic satisfied the spiritual needs of man"; but on a previous page, to some extent following the lead of that distinguished authority, the late Dr. Seligmann, he tells us "the use of amulets is the result of the belief in the powers of the Evil Eye in man and beast". These two statements appear to need some qualification, or at least, reconciliation. In the Mediterranean area, without doubt, the amulet is predominantly used against the evil eye; but among the peoples of simpler culture the amulet is primarily a potent protector against any spiritual influence, vaguely conceived, rather than concerned with the specific concept of a human embodiment of malevolence operating through the eye. In fact, it is difficult not to feel that the author in his account of primitive spiritual beliefs has allowed his views to be too strongly coloured by early Mesopotamian demonology.

Again, the author says: "He [primitive man] required amulets to enable him to beget children, to give him strength, to overcome his enemies, visible and invisible, and above all the evil eye, and to protect his women and children and house and cattle; and his descendants throughout the world have always done the same". But taking the first part of this statement of the objects for which an amulet is employed, the character of primitive beliefs relating to the amulet all the world over would seem to suggest rather that it is not so much to enable man to do these things as to ward off influences that would prevent him from doing them that the aid of the amulet is invoked. Even in the case of the modern mascot of civilisation worn as a 'luck-bringer', so far as the belief is capable of analysis it is just as much a 'bad luck averter' as a 'luck-bringer'. Why is the mascot carried on the bonnet of a motor car? Why were mascots so much in vogue during the War?

The question is of something more than formal import as it implicates a quite definite change in attitude towards the supernatural. The primitive attitude of mind is one of fear; and the 'luck-bringer' implies some form of influence or control. Fear, if not entirely eliminated, has at least been deposed from its dominant position. The transition no doubt may be sought in the spell or incantation, the 'word of power'. If this does not warrant a certain looseness of terminology and definition in the author's more general statements, it may, perhaps, be regarded as justifying him when he comes to deal with matters of detail in his admirable accounts of the various types of spell to be found among Assyrians, Hebrews, Samaritans, and other peoples ancient and modern.

A wider view, in a geographical sense, would have added considerably to the value of the account of the swastika. It is here suggested that the swastika of the terramaricoli was really a cross. America is not mentioned; but it would have been interesting to know what the author thinks of the types and distribution of the swastika on that continent. The waved form in a circle of America also occurs in eastern Asia. Is this significant, or do other considerations outweigh the coincidence?

The contents of this book justify the author's contention that he should have used the term "magic" in the title instead of "superstition". The mere recital of the sub-title would support a claim that it might serve as a text-book of the magic art. Should the reader wish to know what forms of divination were current among the ancients, what rings they wore and why, how they used the waxen image of witchcraft, what were the various theories of numbers, or what virtues they assigned to precious stones, all this and more is here under his hand. Sir Wallis tells us that this book is an answer to the questions he was asked by the public in his department at the British Museum. Truly the curiosity of man about the things that are hidden is insatiable.

(2) Vol. 12 of the *Memoirs* published by the Institute of Ethnology in Paris is a collection of charms and medical receipts which very appropriately may serve to supplement and illustrate Sir Wallis Budge on charms and incantations. The collection is taken from a book purchased by M. Marcel Cohen in Abyssinia in 1910–11—a duplicate copy belonging to one of the priestly class, from which he was apparently prepared to part in the belief that it would not be understood. It consists of charms against magical powers and particularly the evil eye, while a second part is concerned with specific diseases, and ills of various parts of the body. It affords a considerable amount of information as to plants in medicinal use. Numerous taboos have to be observed, and much stress is laid on orientation, both in gathering and in using the plants. The value of the text is much enhanced by the editor's notes and appendices on the various types of spirits and magical beliefs current among the people. These are partly based on information obtained from Abyssinians who were fellow-students with him in Paris.

The Formation of Atolls.

Coral Reefs and Atolls: being a Course of Lectures delivered at the Lowell Institute at Boston, February 1930. By J. Stanley Gardiner. Pp. xiii + 181 (15 plates). (London: Macmillan and Co., Ltd., 1931.) 10*s.* 6*d.* net.

ALL interested in the many fascinating problems of the formation and maintenance of coral reefs, be they marine biologists, geographers, or geologists, have reason to be grateful to the president of the Lowell Institute of Boston. It was as a result of his invitation that Prof. J. Stanley Gardiner delivered a course of lectures at Boston in 1930, and that now we have a volume embodying these lectures, which represent the fruits of thirty-five years' interest in coral reef problems and five years of personal observation on the reefs of the Indian and Pacific Oceans.

While probably many people are aware of the difference between fringing and barrier reefs and atolls, few who have never visited coral reefs have any clear picture in their minds of what a reef is really like. A study of Saville Kent's magnificent pictures of the Great Barrier Reef gives a totally wrong impression. The exposed face of a reef is a buttress of immense strength but certainly not a forest of beauty. In his introductory chapter, Prof. Stanley Gardiner gives an admirably lucid and well-balanced account of the various kinds of reefs, which should correct the previous mental impressions of many of his readers. He also disposes of the too arbitrary distinction which has been made between fringing and barrier reefs, pointing out that an island may possess a fringing reef off one coast and a barrier reef off the other, the two merging into one another, and being usually dependent on the presence of a gently sloping or a precipitous coast respectively.

While the skeletons of corals are the bricks with which reefs are built, the equally important cement which binds together these bricks and covers every exposed, dead surface is provided by the coralline algæ, the nullipores, of which *Lithothamnion* is the best known of the five important genera. On and in the reefs dwell a varied collection of animals and plants (the latter, however, strangely sparse to the eyes of a marine biologist accustomed to temperate seas) which, with the corals and the nullipores, form that characteristic marine community of tropical seas which to a biologist is a coral reef. All these living constituents of reefs, with the parts they play, constructive, passive, or destructive, in the maintenance of that mass of limestone which, to the geologist and geographer, is a coral reef, are passed in brief, yet adequate, review by Prof. Stanley Gardiner.

Of the great, probably vital, significance of the unicellular zooxanthellæ which are invariably present in reef-building corals and all other cœlenterates on reefs, there can be no question. Prof. Gardiner stresses the importance of the oxygen produced by the zooxanthellæ, and suggests also that carbohydrate may be passed from them to the coral. Here it is impossible entirely to agree with him (for reasons which the reviewer has given elsewhere), while the resemblance between the conditions in corals and in *Convoluta* is more apparent than real. The illustration, in Fig. 14, of the gametes of the zoochlorellæ from *Convoluta* suggests, moreover, that the zooxanthellæ possess similar gametes, whereas they are apparently so degenerate as to have lost the power of sexual reproduction.

There can be nothing but praise for Prof. Gardiner's handling of the problem of the origin and formation of atolls. Much of the book is occupied with this matter, and rightly so, for it is the crux of the coral reef problem. How did these limestone rings, their vegetated summits barely rising above the surface of the sea, come to be dotted over the surface of the tropical oceans, surrounded as they frequently are by water thousands of fathoms in depth? The subsidence theory of Darwin and Dana, which has been recently so strongly defended by Prof. W. M. Davis, is here rejected as the explanation of the origin of atolls, and for good reasons. If the atoll has not been formed from a barrier reef by the submergence of the central land mass, then it must have arisen from beneath the sea, and this necessitates the presence of innumerable submerged banks not more than fifty fathoms from the surface. How have these been formed? In the Indian Ocean, which is here regarded as the site of an ancient continent, and in the western area of the Pacific, such platforms may have been formed by the erosion of islands, the process being possibly completed during the last glacial epoch as postulated by Daly in his well-known glacial control theory. But the atolls of the central Pacific, many of them situated on the summit of an isolated peak, cannot have had such an origin.

The only reasonable explanation is surely that supported by Prof. Gardiner, that these atolls are built up on the summits of extinct submarine volcanoes. Falcon Island, which has three times appeared above the surface since 1883, provides positive support for this view, while Admiral Wharton long ago suggested that the ash thrown up by such a submarine eruption would quickly be cut down to the level of wind-wave and current action, about 30-50 fathoms in the open ocean. The growth of corals and nullipores around the submerged slopes of Falcon Island prior to its last eruption in 1927, indicates how quickly corals can establish themselves on a bank of this nature.

The shape of the atoll remains to be accounted for. This was easily explained by the subsidence theory, but it is more difficult when an atoll is regarded as something arising from, and not sinking into, the sea. Here Prof. Gardiner follows Murray; he considers that lagoons have been formed by solution and erosion. While it is difficult to believe that solution plays an important part—coral seas are always saturated with calcium carbonate, and Mayor failed to find any dissolution of calcite by sea-water—yet there can be no gainsaying the great destructive action of the innumerable borers, of which molluscs are the most conspicuous but plants (blue-green algæ) the most ubiquitous. Corals do not flourish within lagoons; whereas outside their powers of growth are at least as great as the powers of destruction, within the lagoons this is not so. Conclusive evidence is given of the enlargement of many lagoons and of the carrying out of suspended coral mud by the ebbing tide. It is suggested that corals in lagoons may be killed by the deposition of amorphous calcium carbonate, produced by the removal of carbon dioxide from calcium bicarbonate by the zooxanthellæ. This, however, needs experimental verification. Moreover, the trade winds possibly have a considerable influence on the moulding of atolls.

All too little is known about coral reefs; there is unanimity about nothing. "Coral Reefs and Atolls" is a concise, admirably illustrated survey of the subject, and represents a definite advance in the elucidation of the coral reef problem.

C. M. Y.

Spherical Astronomy.

Text-Book on Spherical Astronomy. By Prof. W. M. Smart. Pp. xi + 414. (Cambridge: At the University Press, 1931.) 21*s.* net.

A NEW textbook supplying a real need is always welcome. The book now under review is based on lectures given in the University of Cambridge and is essentially designed for the use of students, but will be found to be of great service to astronomers also. Modern developments in astronomy have rendered the older textbooks incomplete, so in addition to the discussion of the usual problems of spherical astronomy, the book contains much new matter, including the essential discussion of such subjects as heliocentric co-ordinates, proper motions, the orbits of binary stars, and the use of photography in precise astronomical measurements, information on which is only to be found in scattered scientific papers.

Much care has been given to methodical arrangement and to the diagrams, which are generally excellent; while, so far as possible, the simplest mathematical tools have been employed, the formulæ being carefully developed, so that no difficulty should be experienced in following the argument to its logical conclusion. Thus, the first chapter is devoted to the proofs and applications of the formulæ of spherical trigonometry, which form the mathematical foundation of the subsequent chapters.

The traditional portion is generally very well done and calls for no special comment beyond the fact that it is reasoned with great lucidity and that great care has been taken with the diagrams.

Not much space is given to practical astronomy, the meridian circle being the only instrument described, presumably because it is the fundamental instrument by which the precise positions of the heavenly bodies are determined that form the foundation on which our knowledge of proper motions, solar motion, etc., is built.

Amongst the newer features is a paragraph on heliographic co-ordinates by which the positions of sunspots and other markings on the sun's surface are defined. In view of the well-established, but imperfectly understood, connexion between sunspots and terrestrial magnetic activity, this branch of astronomy deserves attention. The subject of the proper motions of the stars is adequately treated, and the derivation of the solar motion and also statistical parallaxes of stars are explained.

Photography now plays a most important part in nearly all branches of astronomy, and in positional astronomy the astro-photographic telescope is second in importance only to the meridian circle, to which it has become a natural auxiliary.

The catalogues of the Astronomische Gesellschaft were the product of a very great expenditure of money, time, and energy; they are now being reobserved, not with meridian circles but with photographic lenses, and the work will be completed for a small fraction of the original effort, and, in addition, the positions derived from the photographs will be of much higher accuracy than those in the original catalogues. The chapter on astronomical photography is, therefore, of special interest. Here the errors affecting a stellar photograph, its measurements, and the reduction of the measures are fully and carefully explained, and it is shown how, using rectangular co-ordinates, all errors of the first order are corrected by means of six constants.

It should be observed that though terms of the second order may generally be neglected for small areas, with lenses covering large fields of 5° or more—such as are in use for the re-observation of the A.G. Catalogues—this is no longer the case.

Reverting to the meridian circle, the description of the method of determining the collimation error seems rather laboured, and simpler diagrams would have sufficed. The circle of collimation is a purely instrumental condition, and in no way connected with the azimuthal adjustment, so why introduce the azimuth into the argument ?

The paragraph on planetary aberration does not appear to be quite correct. It is easily shown that the apparent position of a planet at time t is the true position at time $t-\tau$, τ being the aberration time. The usual practice is to antedate the time of observation by the aberration time, thus correcting both planetary and annual aberrations simultaneously.

The diagram illustrating the photographic refractor in paragraph 158 is not very elegant, though this is unimportant; but in the determination of stellar parallaxes, no mention is made of the method of dependences, the very neat modification of the method of least squares invented by Schlesinger and used by all parallax observers.

These points are mentioned in constructive criticism that they may be considered in a second edition, not in detraction of a very excellent work, on which the author is heartily to be congratulated.

Short Reviews.

The Wissahickon Hills : Memories of Leisure Hours out of doors in an Old Countryside. By Prof. Cornelius Weygandt. Pp. xiv + 366 + 10 plates. (Philadelphia : University of Pennsylvania Press ; London : Oxford University Press, 1930.) 17*s*. net.

I LOOKED up the Wissahickon Hills in my large atlas and did not find them ; I discovered Pennsylvania to be an immense State, and that the Alleghany and Blue Mountains tail off in its central parts into a welter of hills and streams. I saw that the author is a professor of English literature, and I thought that this is no book for NATURE. I took the book to bed and I read " The Fox Sparrow ". I had never heard of him, but I was charmed with the " big bouncing fellows " with their " high spirits that come from good shelter and full craws, sunlight and the urge of spring ". " In Praise of Wild Cherry " attracted me next, and this was followed by " The Kentucky Warbler ". I am still a yokel at heart, and I dreamt of my own hills and my father's farm-yard. " The Famous Darking Fowl " came next day, and I have never been able to leave this book alone since.

I do not know the country, but the hills, the streams, the birds, all belong to me and I know their ways. " The Old Stock " gives me my people, unaltered and unchanged for centuries. " We have a good deal of local pride. . . . We are rather sure of ourselves. . . . We are workers and few of us are fond of parade and show. . . . We are still stout walkers. We are fond of out-of-doors. We are unafraid of sweat. . . . We own to an interest in natural science more gladly than to an interest in art ", which " we are not sure that we ought to admit ". " Our Village " might be here, while near by Gilbert White and Richard Jefferies might dwell. They loved to potter and note the little wonders by the way. So does the author, and he is not trying to teach me anything. Emphatically this is a book for NATURE, not, perhaps, to be recommended to professional biologists, but to men who agree with Frost that " The best thing that we're put here for's to see ". Emphatically a book likely to become a classic of Pennsylvania and to attain a permanent place in Anglo-Saxon literature.

J. S. G.

Recent Advances in Analytical Chemistry. Vol. 1 : *Organic Chemistry.* Editor : Dr. C. Ainsworth Mitchell. Contributors : C. L. Hinton, E. J. Parry, D. Jordan Lloyd, H. Chick, D. W. Kent-Jones, G. D. Elsdon, W. Dickson, J. G. King, R. A. Acton-Taylor, H. R. Ambler. Pp. x + 420 + 6 plates. (London : J. and A. Churchill, 1930.) 12*s*. 6*d*.

WITH the enormous output of original literature in science, it is practically impossible for the scientific worker to keep in touch with more than a very limited field of inquiry. In this book a successful attempt has been made to collect and arrange in accessible form the latest reliable information on various sections of organic chemistry applied to analysis. As indicated by the editor, the aim has been to give a brief critical summary of the literature up to a decade ago. Although this volume is called " Organic Chemistry ", a considerable amount of important information on physical chemistry is included; for example, a very thorough review is given on the applications of the polarimeter in sugar analyses, on purification by electrodialysis, on condensation of gases, etc. From that period onwards, progress has been dealt with more fully, and concise working details of new methods are given.

Each chapter is prefaced by a short synopsis and ends with a bibliography. Throughout the text exhaustive references are recorded. The work is critical, and indications are given as to the direction on which further advance is likely. Although the book is restricted to some four hundred pages, a great number of subjects of industrial importance have been reviewed. These include sugar, oils and fats, essential oils, proteins, tannins and cereals, milk products, paper, petroleum, coal and gas. Each section is written by an expert in his own field, and the whole work is thoroughly co-ordinated and ably edited. It is an easily readable book, well printed, and with a good index. It is comparatively cheap as modern prices stand. The reviewer suggests that it is a book that should be in the hands of every analytical chemist. J. REILLY.

Sea-Angling Fishes of the Cape (South Africa): a Natural History of some of the Principal Fishes caught by Sea Anglers and Professional Fishermen in Cape Waters. By C. Leo. Biden. Pp. xii + 304 + 48 plates. (London: Oxford University Press, 1930.) 18*s*. net.

CAPE COLONY extends from the Atlantic to the Indian Ocean. Whereas on the west side there are almost constant conditions owing to the southern current, the waters of the Indian Ocean lave the southern peninsula, during the summer months. This means migration of fish from the north, while many stationary fish must have well-defined seasons of abundance and scarcity of food, although perhaps feeding is a matter of the psychology of the fish themselves, induced by temperature and other physical and chemical changes in the sea. There are also regular breeding seasons and movements induced by these. The author is clear on these matters in the eighteen chapters, on a like number of fish, which he presents to the angler. Eight are strong swimming pelagic fish, and his account of their local names suggests that seven must belong to genera common to the whole southern ocean, the eighth being the North Atlantic tunny, which is a rare visitor.

We are at once attracted by the much varied heads and teeth of the bottom feeders; these are correlated with equally different habits and food. Clearly, the Cape is a locality where colour fluctuations could be conveniently studied, as affected by environment, temperature, etc. Octopi, mussels, and tunicates are important articles of food. Commercial fisheries are not discussed; but the angler is generally a man of intelligence, and he is presented with a most readable and admirably illustrated account of his fish. Scientific details may occasionally be wrong; but the author is to be congratulated on a most useful book.

Leçons sur les conduites. Par Prof. Charles Camichel. (Chaire de mécanique des fluides et applications.) Pp. vii + 101. (Paris: Gauthier-Villars et Cie, 1930.) 30 francs.

THIS monograph gives an account of both experimental and theoretical researches carried out during the last twenty years on pipelines, mainly forming portions of hydraulic installations in south and central France. These researches chiefly concern the waves of pressure propagated along the pipelines, in consequence of the elasticity of their walls and the compressibility of water, when the flow of water is changed more or less suddenly, and also the resonance phenomena associated with these waves. The first chapter treats of pipelines of uniform cross-section and wall thickness, and the second with those of variable section and thickness. The third chapter deals with the effect of reservoirs of air connected with the pipelines, especially in damping down the waves. These three theoretical chapters comprise four-fifths of the book, the remaining portion being devoted to a very brief summary of the design and construction of pipelines subject to high pressures and of the accidents to which they are liable. The book is clearly written and should prove of great interest to hydraulic engineers, as well as to mathematicians interested in the practical applications of hydrodynamics.

Systematic Inorganic Chemistry: from the Standpoint of the Periodic Law. By Prof. R. M. Caven and Dr. G. D. Lander. New edition. Pp. xviii + 510. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 9*s*. net.

CAVEN and Lander's textbook has been known to teachers and students for some years as a carefully written statement of inorganic chemistry based on the periodic system, and it could well supplement any other book in use. It is particularly suited to the needs of the more advanced student who wishes to revise and systematise his knowledge of the subject, and a new edition of the work may be welcomed. The authors have added sections on the modern atomic theory and its bearings on the subject at the end of the book. In view of the rapid changes which are taking place in this part of the subject, it is undoubtedly wise to adopt this plan, the permanent structure of the science being dealt with in the body of the work. The additional sections fit in very well with the general plan of the book. One or two newer discoveries probably came too late for inclusion; for example, the preparation of nitryl chloride, the reactions given not leading to the formation of this substance. The new edition of this excellent textbook may be recommended to teachers and students.

Siam: Nature and Industry. Pp. vii + 324 + 60 plates. (Bangkok: Ministry of Commerce and Communications, 1930.) n.p.

IT is seldom that a book of this nature, issued by a State, presumably for propaganda purposes, can be recommended as having any scientific value. This volume, however, is an exception. It avoids the usual guide-book information and self-congratulatory statements, and contains a number of serious chapters on the scientific aspects of the country. Most of these are written by competent authorities under their own names. Thus the book is a valuable compendium on the geology, fauna, flora, ethnology, agriculture, mining, and other aspects of Siam. It is particularly useful, since accurate information on many matters relating to Siam is not easy to find. Several of the chapters were issued as separate pamphlets in 1926. They are now revised and collected in this volume, with additions, which was prepared for the congress of the Far Eastern Association of Tropical Medicine, held at Bangkok in December 1930. There are several maps and illustrations.

The Architecture of the Solid State.*

By Prof. W. L. BRAGG, F.R.S.

A SOLID body is a mechanical system in equilibrium, an example of atomic engineering, with balance of stresses in the component parts. Analysis by X-ray methods, and more recently by those of electron diffraction, has given us a scale plan of its component parts. To what extent can we explain the way in which the atoms are arranged, and the properties of the body as a whole, by considering the forces which act between the atoms?

A broad generalisation divides solids into three classes—metallic, organic, and inorganic. Though it is easy to cite cases of solids which are intermediate in character, this division into classes is clearly marked, and corresponds to a very fundamental difference in the nature of the bonds which hold the atoms together. Metals are associations of electropositive atoms with each other, organic compounds are associations of electronegative atoms, and inorganic compounds associations of electropositive with electronegative atoms. The fundamental distinction between the laws which govern these associations has been implicitly recognised by assigning to each its own branch of chemistry, metallurgical, organic, and inorganic. The law of combination in inorganic compounds was first foreshadowed by Berzelius, those for organic compounds were founded by Kekulé, and confusion arose in the past from the attempt to bring both classes into a common scheme. The laws of atomic association in intermetallic compounds are again different, and are only now being understood through a study of alloy structures.

The success which has as yet been attained in explaining physical properties by atomic structure is different in these three classes. The structures of the metals are very simple, and were amongst the first to be discovered by X-ray analysis; many alloy structures have also been determined. The difficulty of correlating structures and properties is not due to any lack of knowledge about atomic arrangement, but arises partly because the theory of the metallic state is very complex and as yet incomplete, and partly because the mechanical properties of the metals, which are so important to us, depend rather on the destruction of the perfect crystal than on its behaviour as an ideal crystal. Knowledge in this field is mainly descriptive. On the other hand, those organic substances the physical properties of which as solids are most interesting are very complex forms, such as cellulose or rubber. The difficulty here of giving even a descriptive account of the dependence of properties on structure is mainly that of discovering the atomic arrangement. This is one of the obvious fields in which to concentrate all the resources of X-ray technique in future. Such successes as those which Mark has had with cellulose and Astbury with the wool fibre show its interest and possibilities, but in all cases the structures can as yet be only guessed.

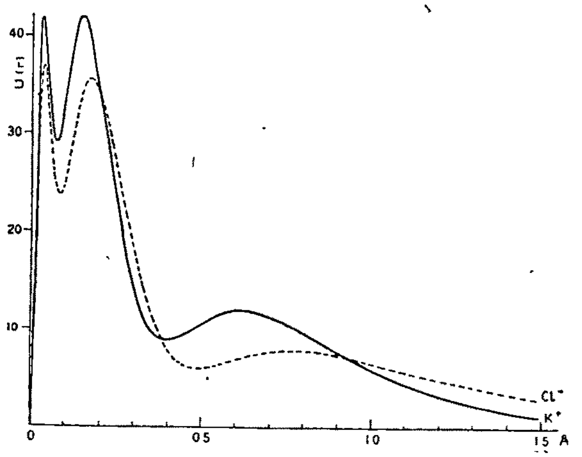

FIG. 1.—The radial distribution of electrons in the ions K and Cl⁻. The peaks in each curve of distribution represent the *K*, *L*, *M* electron groups, containing two, eight, and eight electrons respectively (Hartree).

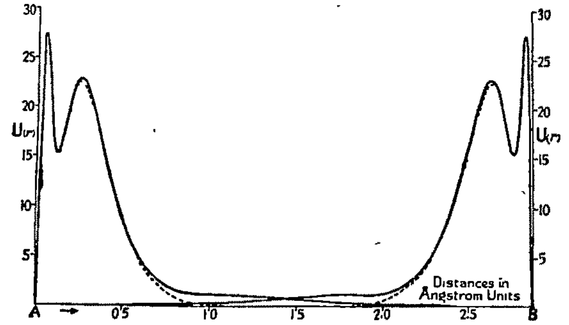

FIG. 2.—The ions Al^3 are shown by the dotted curves, at a distance apart of 2·86 A. as in the crystal of aluminium metal (James, Brindley and Wood). The distribution representing the remaining electrons is almost entirely confined to the space between the ions (metallic bond).

In comparison, the inorganic solids are not of such great technical importance, but I propose to discuss their properties because a more complete story can be told. Not only are the structures well known, but also the interatomic forces can to a large extent be treated quantitatively. The landmark in this field is, of course, Born's great work on the dynamics of the crystal lattice, and it is to the inorganic compounds that his ideas have been mainly applied.

The reason for the success in treating the inorganic crystal is that it can be regarded to a large extent as a problem in electrostatics. The typical crystal is built of component parts which are charged positively and negatively. These parts may be simple charged atoms or 'ions', or they may be charged groups of atoms. Further, the forces of repulsion which keep the ions apart and prevent their structures intermingling can be simply expressed, and their strength quantitatively estimated. So a theory of the physical properties of the solid can be built up, a few aspects of which I wish to discuss.

What is the justification for supposing that electrostatic forces bulk so largely in these compounds? It lies in the fact that when two ions approach each other, the force of repulsion which prevents further approach sets in when the structures have scarcely penetrated at all into each other.

---

* Kelvin Lecture delivered before the Institution of Electrical Engineers on April 30.

The nucleus of an atom is surrounded by an atmosphere of electrons, a kind of space-charge which exactly (neutral atom) or nearly (ion) neutralises the positive charge on the nucleus. The former idea of a series of electron orbits has been replaced by a wave-mechanical distribution which cannot be visualised. It can be represented in a way which is a very good approximation for many purposes by supposing each electron to move in the field of the nucleus and the other electrons, representing it by the 'smeared out' continuous distribution which the solution of the wave equation gives, and then taking the electron atmosphere to be the sum of these distributions. These atmospheres have been worked out for many atoms, the most accurate results being those of Hartree. Instead of definite electron orbits, we get a continuous distribution with spherical symmetry which may be thought of as the density of the electron atmosphere, or probability of finding an electron in unit volume at different distances from the nucleus. A convenient way of showing the electron distribution is to plot U_r against the distance from the nucleus r, where $(U_r)dr$ is the number of electrons between r and $r+dr$. Such a curve for chlorine, which has a charge of $17e$ on its nucleus, and is surrounded by eighteen electrons, is shown in Fig. 1. The distribution has peaks which correspond to the K, L, M electron groups of atomic theory.

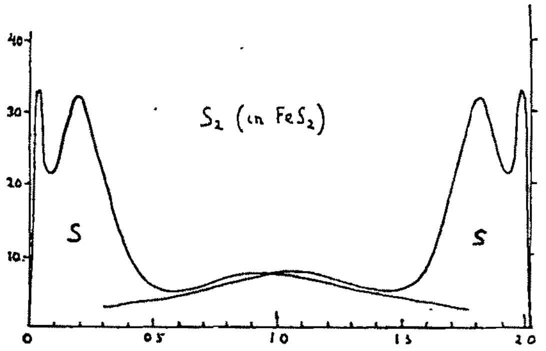

FIG. 3.—The group S_2 in FeS_2, iron pyrites. The distance between the atoms (2·05 A.) is so small that the M shells overlap (non-polar bond).

A striking feature is the rapid rate at which the electron atmosphere thins out as the distance from the nucleus increases. For example, the electron density in various parts of the chlorine ion is as follows, the figures representing the number of electrons per cubic angstrom unit $(10^{-24}$ cm.$^3)$.

K shell	3250
L shell	111
M shell	1·00
At r = 1·84 A.	0·04

The last distance of 1·8 A. is called the 'ionic radius' of chlorine. This theoretically indefensible, but extremely useful, conception of ionic radii expresses the fact that ions in crystals appear to take up a certain amount of space. For example, sodium has an ionic radius of 1 A., chlorine of 1·8 A., and the two ions are 2·8 A. apart in sodium chloride. We may take it here as representing the point where the overlapping of one ion by another takes place. We can see, therefore, that the repulsive force sets in when an extremely tenuous part of each electron atmosphere is involved, in the case of chlorine only 10^{-5} of that in the K shell.

The difference between the three types of interatomic bond is shown in a striking way if we take these atomic models, set them distances apart, such as are found in actual crystalline structures, and see to what extent the electron atmospheres overlap. Fig. 2 shows the state of affairs in an aluminium crystal. The aluminium ions Al^{3+}, shown as dotted lines, are separated by a wide gap. This interspace is occupied by the valency electrons, and metallic properties suggest that these electrons are not bound each to its own atom but are shared by all.

Fig. 3 shows the group S_2 in iron pyrites, FeS_2. The bond between the sulphur atoms is of the non-polar type, such as characterises organic compounds, and the two atoms are so close that there is a merging of their M shells. The two structures combine to form a twin structure like a larger atom with two nuclei. Contrast with these the series of polar crystals shown in Fig. 4 (taken from a paper by Brindley). The structures are of the sodium chloride type in which there is a simple alternation of positive and negative ions, and it is seen that the ions scarcely overlap at all. The diagram exaggerates the extent of overlapping, because the curve measures the distribution of electrons in complete spherical shells all round each nucleus, whereas the ions come in contact at one point only.

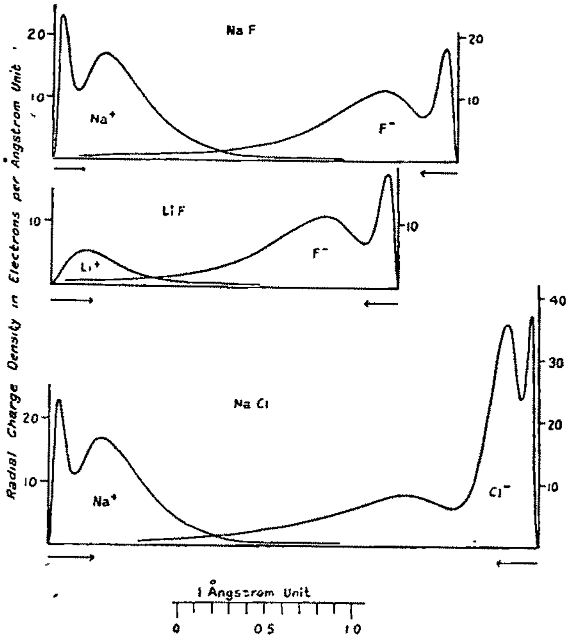

FIG. 4.—The electron distribution in compounds of the sodium chloride type (Brindley). The ionic structures overlap at points where the electron density is extremely small (polar bond).

The first success of Born's theory lay in explaining the heat of formation of these compounds. Suppose the sodium and chlorine ions to remain in regular array, but to be widely separated, and then allow the whole structure to collapse uniformly, ending in the sodium chloride crystal. The energy of the electrostatic field between the ions is reduced in the process, just as when the plates of a condenser come together. This energy can be calculated, and a correction due to the work done against the repulsive forces can be worked out. The latter is small because it only comes into play at the very end of the process. Born showed that the calculated loss of energy was in accord with the heat of formation of the crystal.

(*To be continued.*)

Determination of Position in High Latitudes, with Particular Reference to Aircraft Observation.

By C. J. STEWART, O.B.E.

THE determination of position from land or air observations in high latitudes is rendered difficult, apart from conditions of temperature, by the unreliability of the magnetic compass and gyroscopic compass. On aircraft the latter is not yet a practicable instrument. Hence, astronomical methods must be utilised. In the consideration of any method of air navigation to the poles it must first be made clear that, even with assumed perfectly accurate instruments and accurate observations with them, astronomical observations from an aeroplane can give an exact position in two cases only: (1) by the observation of two stars; (2) by choosing the time of flight so as to render possible simultaneous observations of both sun and moon. The first case implies that the flight takes place at the season of perpetual night, and need not therefore be considered. The limitations of the second case are increased by the known inaccuracy of any form of sextant used in the air. Broadly, while sextant observations on the ground may be relied upon to give position within, say, one to three miles, aerial observations can only be relied upon to give position within about ten miles, and it is usually necessary to take the mean of a number of readings to secure this result. The use of automatically stabilised aircraft may render a somewhat more accurate location possible, but the utility of such aircraft under polar conditions can scarcely be regarded as established.

In view of such limitations, reliance has to be placed upon other means of navigation. Radio direction-finding is unlikely at the present stage of development to be of use, since its accuracy at a range of, say, four hundred miles would not, under favourable conditions, give position in line to within twelve miles. Radio signalling is, however, of value for providing exact time signals. The navigator is therefore compelled to rely upon the use of the most accurate instruments for—

(1) indicating direction, and
(2) indicating ground speed in magnitude and direction.

This, of course, is virtually the oldest method of navigating, namely, dead reckoning.[1] The instrument used for indicating direction must be some form of sun compass or a gyro azimuth. Of these alternatives, where the sun is available, the sun compass is likely to be the more accurate, since an instrument measuring the sun's position, in conjunction with an accurate chronometer, would be simpler and less liable to variation than any form of gyro azimuth at present known. The feasibility of using gyroscopic devices will be referred to later, but since the sun compass formed an essential part of the equipment of both Amundsen and Byrd in their polar expeditions, a description of such an instrument is necessary.

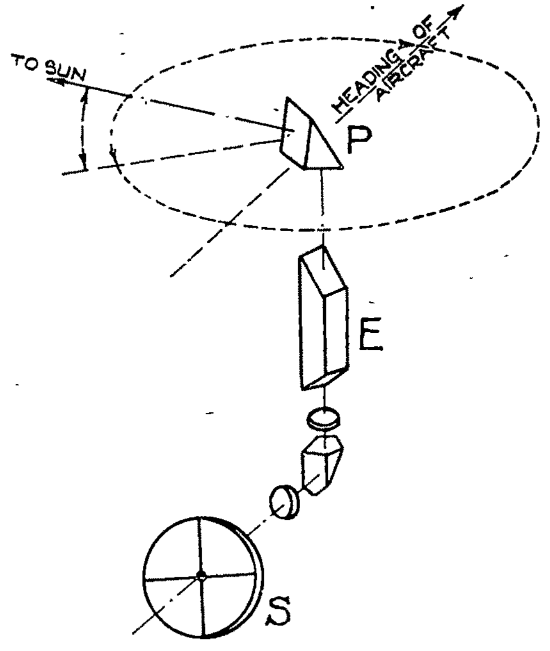

FIG. 1.—Optical arrangement of the Goerz sun compass.

Instruments for measuring ground speed and direction are quite well known[2] and, in their use under polar conditions of temperature, present no great difficulty.

Since the sun is above the horizon during the exploring season, and since it is always at a low altitude, the sun compass forms a very suitable instrument for determining directions. The Goerz sun compass was constructed specially for the Amundsen expedition in 1925 and, according to reports, gave very satisfactory results.[3]

This instrument comprises an optical arrangement which throws an image of the sun on a screen S (Fig. 1), when the aircraft is on the desired course. The reflecting prism P may be rotated about a horizontal axis and set according to the declination of the sun. It may also be rotated about a vertical axis and set according to the time of day and the desired course. When the settings have been made, a clock mechanism keeps the prism in the correct orientation. After reflection, the light passes through the erecting prism *E*, which is rotated at one-half the speed of the prism *P*. The light then passes through a lens system to the screen. A vertical line on the screen serves as a lubber line. The compass must be installed with the horizontal part of the optical axis parallel to the longitudinal axis of the aircraft.

Such an instrument will give, of course, a space direction and not an earth direction. Thus, if it is set to give some definite meridian at any given position of the aeroplane, the track of the latter will not be in the direction of the pole unless the position is chosen to lie on that meridian.

By the use, then, of the sun compass and ground speed indicator (incorporating, of course, a drift indicator) the navigator to the pole must attain his object by careful course plotting based on dead reckoning.

Since the determination of ground speed is a vital matter in such dead reckoning, considerable judgment and care is needed in the method of securing a reading. One method is to time the passage of a ground object past two wires on a sight which is so set as to incorporate the height of the aeroplane above the ground, the method itself being based on similar triangles.

This method is liable to error, of course, where the height of the ground is not known exactly. In such a case, the wind speed is determined by flying the aeroplane on different courses and plotting the track or course made good. From two such readings the wind speed and direction may be determined, and thus from a knowledge of the air speed the ground speed on any given course may be obtained.

As an illustration of the difference between ground and air technique for position-finding in high latitudes, the method used by Peary in his journey to the north pole in 1919 may be compared with the method used by Byrd in his flight to the north pole in 1926. Peary followed closely a meridian from the base camp, using dead reckoning for direction and distance, occasionally using a sight on the sun for correcting his distance. When his dead reckoning calculations indicated that he had reached the pole, a meridian sight on the sun showed him that he had covered a distance which would have taken him exactly to the pole had his direction been correct. This sight by itself, however, did not suffice to locate his position on the earth, but a sight on the sun from the same position eighteen hours later in a direction at right angles to the first observation gave his location as five miles from the pole. Byrd in his flight to the north pole in 1926 flew from a known base in a direction indicated by the sun compass and at a ground speed calculated from drift and airspeed observations. At satisfactory intervals of time, observations of the elevation of the sun were taken, which gave him position lines cutting his plotted course at varying angles, some at suitable angles for checking his latitude and distance, others at angles for checking his longitude, and thus his direction.

It will be at once apparent that such aerial observations taken with instruments which, under the best conditions of usage, are subject to error, are less exact than those taken on the ground from the same position at suitable time intervals.

Byrd and his companions in the south polar flight in November 1929 used the dead reckoning method with two sextant readings of the elevation of the sun. Byrd does not claim any considerable accuracy for these sextant observations. His method, which appears as a fine example of dead reckoning navigation, deserves comment. His navigational equipment, comprising a sun compass, drift and ground speed indicator, and airspeed indicator, were all thoroughly tested at the base before the flight to the pole, and were, of course, used with the greatest skill. Any errors due to the use of this equipment can therefore be regarded as being as small as human effort could make them.

The flight may be divided into three parts—

(*a*) From the base camp to the trail camp of the geological party close to the mountains;
(*b*) from the trail camp to the south pole and the return to the supply depot at the foot of the mountains;
(*c*) from that depot to the base camp.

The base camp and the trail camp had been located by ground observations, and these positions may be regarded as accurate to within one or two miles. The geographical position of the trail camp had been determined by Dr. Laurence M. Gould, the geologist of the expedition, who had also determined the position of the east portal of the Liv glacier, which was a short distance nearer the pole than the camp.

The parts (*a*) and (*c*) of the flight need be discussed only briefly, since the territory had been well explored, both from the air and on the ground, and the navigation of it served mainly as a check upon the accuracy of the instruments. The start was made from the base camp at 3 h. 30 m. Nov. 29, 1929, Greenwich Civil Time. At 8 h. 16 m. G.C.T. the plane reached the trail camp, 327 nautical * miles nearer the pole and 361 miles from the south pole. On leaving the trail camp the same course was maintained for 16 miles, when it was changed 30° to the right towards Liv glacier, where a check was obtained from a predetermined position—the east portal of the glacier. Here, owing to difficulty in obtaining sufficient height, the course was changed and continued for 50 miles up and over the glacier. Reaching the plateau, the course was made along the 171st meridian for the flight south to the pole. The position of the aeroplane relative to Mount Nansen and Mount Ruth Gade checked the dead reckoning position from the trail camp. At 10 h. 20 m. the plane was placed on the 171st meridian at parallel 86° 13′, and the sun compass set along that meridian to the pole 227 miles away.

---

* All the distances referred to are in nautical miles.

Here, then, one may pause to consider the accuracy with which this actual position was attained in view of the difficulties experienced in reaching the position and the deviation from the course laid down. Subsequent instrumental observations appear to indicate that no considerable error was introduced by the manœuvre. Heading south, and holding the plane as closely as possible to the 171st meridian by the aid of the sun compass and the drift and speed indicator, it was estimated that the pole was reached at 13 h. 14 m. Greenwich Civil Time. In this flight it was noted that at local midnight at that meridian, when the sun was beyond the pole and in line with the meridian, the nose of the plane was pointing directly at the sun and a corresponding indication was given by the sun compass, so indicating that the sun compass was showing the direction of the 171st meridian. There was no outside check on how closely the aeroplane was holding to this meridian except the landfall made on the return journey. Two rough checks on the dead reckoning determination of the distance flown were made at 12 h. 38 m. and 13 h. 6 m., when sextant elevations of the sun were obtained. These gave positions from the pole of 56 and 2 nautical miles respectively. The corresponding dead reckoning positions were 50 and 11 nautical miles. Byrd discounts the accuracy of the sextant observations owing to the errors introduced by the motion of the aeroplane, and experienced aerial navigators will agree with his judgment. These checks, nevertheless, serve a very useful purpose since they were the only independent evidence available, and the distances are of the same order as those given by the dead reckoning calculations.

At 13 h. 14 m. it was reckoned that the pole had been reached, but deviations of the plane to the right and left of the course for a distance of three miles, and covering a further directional distance of about five miles, decreased any error in the actual location of the pole so far as the flight was concerned. The aeroplane was headed back over the pole and flown down the 168th meridian at 13 h. 25 m., which should have made the course for the Axel Heiberg glacier. At 15 h. 30 m. the glacier was sighted.

It will be seen, therefore, that, by the skilled use of the drift and ground speed indicators and the sun compass, the navigation had been sufficiently precise to locate the close vicinity of the pole, the sextant observations serving as the check on the dead reckoning determination given by the speed indicator and compass.

It will be noted that a journey of some seven hundred miles was made in a period of about ten hours. In a land exploration a normal distance in such a time would be about ten miles, during which time observations of the position can be made as necessary, although the difficulty of making these relatively exact determinations is far greater than that of obtaining data in an aircraft.

Although gyroscopic methods of position finding in high latitudes suggest themselves as theoretically feasible, it is not profitable in the present state of the art of using aerial or other gyroscopes to discuss such means for position finding. Not only would such gyroscopes have to be far more exact in functioning than any so far produced for aerial work, but also the conditions of temperature would inevitably introduce such troubles in running that prolonged and arduous research would be necessary to devise the apparatus. The dangers of relying solely upon such means in an aerial polar expedition are so numerous as to render any such scheme impracticable.

Obituary.

PROF. F. W. CLARKE.

FRANK WIGGLESWORTH CLARKE, born on Mar. 19, 1847, at Boston, Massachusetts, was well known among inorganic chemists, mineralogists, and geologists in Great Britain. For mineralogists and geologists his "Data of Geochemistry" was a handbook full of invaluable information, not in other ways readily accessible, especially at the time of its first publication in 1908. In addition to his work directly related to geology and mineralogy, he did important work on atomic weights and thermochemical constants. He was chairman of the International Committee on Atomic Weights in 1900; president of the American Chemical Society in 1901, of the Washington Academy of Arts and Sciences in 1911, and of the Washington Philosophical Society in 1896. He was a foreign member of the Geological Society of London; an honorary member of the Chemical Society, of the Mineralogical Society, and of the Manchester Literary and Philosophical Society; and a corresponding member of the British Association and of the Geological Society of Edinburgh. He was given the honorary degree of D.Sc. by Victoria University, Manchester, and LL.D. by the University of Aberdeen.

Clarke graduated at Harvard in 1867. His first teaching post was in the Department of Chemistry at Cornell University, Ithaca, New York, in 1869. He became professor of chemistry in Cincinnati University, Ohio, in 1874. His first paper, in 1868, was "On a New Process of Mineral Analysis". At Cornell he turned his attention to the determination of atomic volumes of solids and liquids as well as to inorganic analytical methods, and during his professorship at Cincinnati he published, in the *Smithsonian Miscellaneous Collections*, a series of articles on "The Constants of Nature", concluding, in 1883, with the recalculation of atomic weights, of which a new edition was published in 1898.

In 1883 Clarke joined the U.S. Geological Survey and became chief chemist, a post which he held until 1925. He was also professor of mineral-chemistry in the George Washington University at Washington, of which University he was made a doctor of science in 1899. It was during his service with the Geological Survey that Clarke produced the bulk of his work. In the Royal Society's catalogue for 1884–1900 there appear 39 titles under his own name alone and 17 with other authors. His work in this period included important papers on the constitution of silicates, and especially on the micas and chlorites, and in 1889 a paper, destined to be of great interest in later years, on a platiniferous nickel ore from Sudbury, Ontario. The "Data of Geochemistry" did not appear until 1908: it is now in its fifth edition.

The War period seems to have diverted Clarke's attention from minerals, and he produced a series of papers on the inorganic constituents of marine invertebrates, mostly written in collaboration with G. Steiger or W. C. Wheeler, and now summarised in one volume, of which a second edition was required in 1922. In this year he published a paper on the average composition of igneous rocks in conjunction with H. S. Washington, and this was followed by one on the composition of the earth's crust in 1924. This and the fifth edition of the "Data of Geochemistry" were his last publications. He was then seventy-seven, but still enjoying excellent health, when he paid a visit to England, renewing his acquaintance with many friends.

WE regret to announce the following deaths:

Prof. Arthur Starr Eakle, professor of mineralogy at the University of California, aged sixty-seven years.

Prof. A. Forel, formerly professor of psychiatry in the University of Zurich, pioneer of neurology and brain anatomy, and author of the "Social World of Ants", aged eighty-three years.

News and Views.

No one will deny that Great Britain, and indeed the whole world, is passing through a phase of acute economic and industrial depression. We have referred to this repeatedly in our columns and urged the importance of research in providing new outlets for trade, new methods and new materials. Research in all departments of life must at all costs go on, and we had hoped that the days were gone when the so-called unproductive research department was the first to go when economy was called for. Yet 'research' and 'education' are prominent among the recommendations submitted by the Committee on National Expenditure (Cmd. 3920. London: H.M. Stationery Office. 4s. net). Apparently research is still regarded as an expensive luxury. The report emphasises the point raised in our leading article that public opinion is not yet educated to the value of the scientific worker and of scientific method to the community. The Committee on National Expenditure consisted of Sir George Ernest May (chairman), Mr. P. Ashley Cooper, Sir Mark Webster Jenkinson, Mr. Charles Latham, Lord Plender, Mr. Arthur Pugh, and Sir Thomas Royden—the omission of any person of scientific eminence will be noted—and in its terms of reference it was charged to make recommendations for "effecting forthwith all possible reductions in the national expenditure on Supply Services". Among the recommendations are the abolition of the Empire Marketing Board, abandonment of the new programme of research in civil aircraft, reduction by 12½ per cent of expenditure on research and technical development for defence, wholesale reduction at the Ministry of Agriculture and Fisheries, including 50 per cent reduction of grants for agricultural education and limitation of grants for research, and a quarter of a million reduction in the grant to universities. We would urge the Cabinet committee which is to examine these proposals to consider very gravely the proposed restriction of research which, in the long view, can only impede the return of prosperity.

JOHN DRYDEN, the poet, was born three hundred years ago, and in the month of August, though chroniclers do not record anything more exact than that it was on or about Aug. 9, 1631. Dryden was interested enough (as were other literary men of his time, for example, Edmund Waller and William Hammond) to subscribe the foolscap obligation or resolution, dated Dec. 5, 1660, approving the formation of an organised society for the purpose of prosecuting 'Experimental Philosophy'. This was the germ of the Royal Society of London, incorporated a little later, and of which Dryden became an original fellow. He had signed the resolution, it may be mentioned, as "Driden". Born at Aldwinkle, Northamptonshire, Dryden was the eldest of fourteen children. He entered Westminster School as a King's scholar, proceeding afterwards to Trinity College, Cambridge. In Dryden's poem "Annus Mirabilis", written before his return to London at the close of the year 1666, he apostrophised the newly founded Royal Society. Clearly he regarded it as embodying an intellectual awakening of high intent. Dryden lived in Gerrard Street, Soho, and he died there on May 1, 1700, and was buried in Westminster Abbey.

ON July 28 a memorial tablet to Thomas Earnshaw, the horologist, was unveiled outside the Church of St. Giles-in-the-Fields, Bloomsbury, by the Astronomer Royal, Sir Frank Dyson. The tablet has been erected by the Clockmakers' Company and the British Horological Institute. Like his predecessors, Graham and Harrison, and his contemporaries, Mudge and Arnold, Earnshaw came from the country, having been born at Ashton-under-Lyne, Lancashire, on Feb. 4, 1749, but for many years he had a business at 119 High Holborn. To him is ascribed the merit of devising the chronometer escapement and compensation balance precisely as they are now used, while it was he and Arnold who first produced chronometers in large numbers and at moderate cost, thus rendering service of the utmost value to navigation and commerce. His improvements were recognised by the Commissioners of Longitude, and he was awarded £3000 by the Government. His death took place in Chenies Street, Bedford Square, on Mar. 1, 1829, and he was buried in St. Giles-in-the-Fields, where it was his custom to worship. He had published a pamphlet in 1806 entitled "Explanation of Timekeepers constructed by the Author and the late Mr. John Arnold", and another in 1808 stating his own claims to the invention of improvements in timekeepers.

IMPORTANT changes in the archæological service in India are foreshadowed in a dispatch from the *Times* correspondent at Simla, which appears in the issue of July 31. He states that the Government of India proposes to submit to the autumn session of the legislature a bill which will place all archæological investigation under the Government of India instead of under the provincial governments as heretofore. It will empower the Government of India to make rules governing work by private investigators and regulating the disposal of the finds. Further, provision will be made to facilitate the co-operation of non-official scientific organisations, Indian and overseas, in archæological exploration. The need for such cooperation has been felt in India for some time. This may have been accentuated by the discovery near Ambala, some two years ago, of remains of the Indus Valley civilisation. An appeal for such co-operation, made not long after the discoveries at Mohenjodaro and Harappa, produced offers of expert assistance; but the obstacle to extended investigation has been a lack of funds. In view of these later finds, it is expected with confidence that further exploration will produce evidence to show an eastward extension of this early civilisation, possibly into the Ganges basin; but systematic investigation with this objective is precluded unless assistance, financial and other, is attracted by the possibility from sources other than official.

THE Indian Research Council of the Royal Anthropological Institute is already in touch with archæological, as well as other branches of anthropological, research in India; but unfortunately it has, at the moment, no funds to enable it to carry on active research in India on the lines on which the Institute is already conducting investigations in another archæological field. It may not be out of place, however, in this connexion to mention another activity of the Royal Anthropological Institute with reference to India which should be of considerable utility at the present juncture in making the public more intimately aware of conditions in that country—conditions which, as has been pointed out time and again, have a vital bearing upon problems now under discussion, but upon which the general public is but ill-informed. The Institute's Indian Research Committee, acting under the direction of the Council, has arranged for a series of public lectures to be delivered in the coming autumn which will deal with the races and cultures of India. The session will be opened by the Marquess of Zetland on Oct. 12 with a lecture on "India, Past and Present". The lectures to follow will be: Oct. 19, Prof. F. W. Thomas—"Kings and Emperors of Ancient India"; Oct. 26, K. de B. Codrington—"Indian Sculpture"; Nov. 2, Col. T. C. Hodson—"Hillmen and Headhunters of Northern India"; Nov. 9, F. J. Richards—"Caste and Creed in Southern India"; Nov. 16, J. V. S. Wilkinson—"Mughal Court Painting". The lectures will be delivered at University College, London.

THOUGH many obituary notices have been written of the late Sir Charles Parsons, it is probable that some time will elapse before a biography worthy of him is available. In the meantime, however, it is to be hoped that some of those who knew him best will not fail to place on record their recollections, for the value of such records will increase with the passing of time. Among the fullest obituary notices we have seen is that by Sir Alfred Ewing contributed to the *Proceedings of the Royal Society*. All too brief as this is, it yet contains much of interest not to be found elsewhere. Born a year after Parsons, Sir Alfred was the first to make an independent trial of a condensing steam turbine; it was on his advice that the radial flow turbine now preserved in the Science Museum was installed at Cambridge, and later on he conducted the trials of the historic *Turbinia*. For forty years Sir Alfred Ewing enjoyed the friendship of Parsons, a friendship which "continued without a break or cloud". Another friend of Parsons was Mr. J. Golder, who from March to June contributed a series of articles on the great engineer to the *New Age*. Towards the end of his life Parsons appeared to Mr. Golder as a 'retired admiral': "Blue reefer suit. Fresh ruddy complexion. Dreamy blue eyes. He was quite unconscious of what he had done. His service, like the navies he transformed, was the service of the silent."

THE habit from which they take their name makes flying-fish so conspicuous and invites observation so much that it is curious to find there is still difference of opinion as to whether they really fly or only use their pectorals as parachutes. In the July-August number of the *Scottish Naturalist* (p. 121), Mr. W. L. Calderwood gives some notes on these fish, as observed in calm weather in the Arabian Sea. His observations were made carefully with prism glasses, and led him to the conclusion that the pace, which was very uniform, was maintained by the use of the pectorals at short intervals. Although it could not be seen, at a long distance from the ship, whether these fins were vibrating or not, it seemed to him that a flight extending sometimes even to 150 yards, and performed at only about a foot above the surface, could not have been kept up except by renewed impulses from the fins. This was exactly the impression formed by the writer of this note after repeated naked-eye study of these fish on a first voyage into the same part of the world. They were seen at times to vibrate their fins when clear of the water, as well as when touching it with the tail, as is generally admitted and very carefully described by Mr. Calderwood in the paper alluded to. The impression their flights left was that of the starting flutter and patter of the moorhen, continuing as the glide and whirr of the partridge, with the difference that in the fish the end of the first glide was generally also that of the flight.

THE Medical Research Council announces that it has appointed a Therapeutic Trials Committee, as follows, to advise and assist in arranging for properly controlled clinical tests of new products that seem likely, on experimental grounds, to have value in the treatment of disease: Prof. T. R. Elliott, physician to University College Hospital, London (*chairman*); Sir E. Farquhar Buzzard, regius professor of physic, University of Oxford; Dr. H. H. Dale, director, National Institute for Medical Research; the Right Hon. Lord Dawson of Penn, president, Royal College of Physicians, London; Prof. A. W. M. Ellis, physician to the London Hospital; Prof. F. R. Fraser, physician to St. Bartholomew's Hospital, London; Sir John Parsons, ophthalmic surgeon to University College Hospital, London; Dr. J. A. Ryle, physician to Guy's Hospital, London; Sir John W. Thomson-Walker, consultant urologist to King's College Hospital, London; Mr. Wilfred Trotter, surgeon to University College Hospital, London; Prof. D. P. D. Wilkie, surgeon to the Royal Infirmary, Edinburgh; and Dr. F. H. K. Green (*secretary*). Conditions have been the subject of discussion and agreement between the Medical Research Council and the Association of British Chemical Manufacturers, under which the Therapeutic Trials Committee will be prepared to consider applications by commercial firms for the examination of new products, submitted with the available experimental evidence of their value, and will arrange appropriate clinical trials in suitable cases. The Committee will work in close touch also with the existing Chemotherapy Committee, which is engaged for the Medical Research Council in promoting researches aimed at the discovery and production of new remedies.

THE first regular world-wide broadcasting service from the southern hemisphere has now been inaugurated by Amalgamated Wireless (Australasia), Ltd. The programmes are transmitted daily from Sydney, 2ME, and from Melbourne, 3ME, on the wave-length of 31·28 metres. Those who possess short-wave sets should listen in and help the undertaking by sending reports to Amalgamated Wireless at Australia House, Strand, London, W.C.2. The time-table (G.M.T.) of the transmissions from Sydney is as follows: 05·00 to 07·00 for American countries bordering the Pacific; 09·30 to 11·30 for islands of the Pacific and eastern Australia; 11·30 to 12·30 for Japan, China, and India; 19·00 to 21·00 for Great Britain, western Europe, and South Africa. All programmes will have included in them the laugh of the Kookaburra. The transmissions take place on Sundays at the same times. Melbourne, 3ME, transmits on the same wave-length from 10·00 to 11·30 every Wednesday and Saturday.

THE International Union of Geodesy and Geophysics, at its meeting at Prague in 1927, invited the Argentine Republic to co-operate in the International Time Service. In a recent circular letter (in English) the General Director of the Military Geographic Institute announces that the Provisional Government of the Argentine, by a decree dated Feb. 3, 1931, charged the Institute with the transmission of rhythmic time signals, by short wave, twice daily. The service commenced on June 1, 1931, transmission taking place from the powerful station of the International Transradio Company at Monte Grande. The signals are transmitted (*a*) from $11^h\ 45^m$ to $11^h\ 50^m$ G.M.T. through the transmitter *L.S.F.* in 19,600 kc./s. (15·30 m.), using 14 kilowatts, directed by a reflector towards Europe; and (*b*) from $23^h\ 45^m$ to $23^h\ 50^m$ G.M.T. through the transmitter *L.S.D.* in 8830 kc./s. (33·97 m.), using 16 kilowatts, directed towards Europe and North America by the aid of a bi-directional antenna without reflector. The time-station is at the Institute at Belgrano, $3^h\ 53^m\ 44{\cdot}964^s$ west of Greenwich, according to the Potsdam-Buenos Aires longitude determination made by the Institute in 1927–28. The Institute offers to send monthly, to anyone interested, a list in Greenwich sidereal time of the times of reception of the signals in Belgrano itself; and the co-operation of other institutions and observers is invited in the reception of these signals, of which details are given in the circular.

THE recent broadcasts of the song of the nightingale made by the B.B.C. this year, which have been such a popular item, especially abroad, have led to various rumours in the press. We have been told that many of the listeners have distinctly heard the scratch of the needle which accompanies gramophone records, and have suggested that records have been made of the singing so that listeners need never be disappointed. Another and more serious accusation is that birds have been caught, put into cages, and forced to sing into the microphone by gentle persuasion or otherwise. The extraneous noises heard, such as the striking of village clocks, distant motor horns, etc., could easily have been added to mislead the listeners. In the *Wireless World* for July 29 there is a letter from the owner of the house at which the broadcasts were made, and at which he was present, saying that they were genuine transmissions of the bird's singing, and that there was no necessity to have resort to other methods.

THE Convention of the International Commission on Illumination, of which Mr. C. C. Paterson is president, will be held in London in September next. The meeting will be made notable by the flood-lighting of several historical buildings in London in the evenings. Recently Londoners had an opportunity of witnessing experimental flood-lighting of Westminster Abbey and other notable buildings. One of the most successful examples of flood-lighting is Dover Castle, a description of which appears in the Osram G.E.C. *Bulletin* for July. The flood-lighting has proved so successful that it has been decided to make it permanent. Twelve powerful projector lamps are used, each taking a thousand watts. Situated as it is on the top of a hill, it is visible for miles around and everyone is pleased with the effect produced. Ships passing many miles out in the English Channel can see it plainly, and in clear weather it is a picturesque sight from the French coast. It is one of the best examples of flood-lighting yet carried out in Great Britain.

THREE new automatic wireless beacon stations are to be erected on the Uruguayan coast by the Marconi Company on behalf of the Hydrographic Department of the Government of Uruguay. The stations, which are expected to be placed in commission in the summer of 1932, are to be of the fixed omnidirectional type. Two of the transmitters will be installed in lighthouses —at Lobos Island and Cape Polonio; and the third in the English Bank Light Vessel. The transmitters are designed to operate on two definite wave-lengths, one of 600 metres and one between 950 and 1050 metres. In addition, the Marconi beacon in the English Bank Light Vessel will operate in conjunction with a submarine sound signalling device, so that navigators can estimate their distance as well as their direction from the light vessel. It is understood that the beacon station at Lobos Island will transmit on a wave-length of 1000 metres. The beacon station at Cape Polonio will transmit on the wave-length of 1050 metres. The allotment of a distinctive signal for the English Bank lightship has not yet been finally decided, in view of the special arrangements for the transmission of a series of dots in conjunction with the submarine signal device.

AN excellent example of the importance of research in industry is the invention of 'paragutta', a material with which the new telephone cable provided to supplement the growing traffic between the United States and Cuba, is insulated. For the past seventy-five years, the standard materials for insulating deep-sea cables have been gutta-percha and balata. Paragutta is a mixture of about fifty per cent gutta-percha, forty per cent rubber, and ten per cent hydrocarbon wax. Its mechanical qualities are fully equal to those of gutta-percha, its electrical stability in water is the same, but it has much better specific electrical properties. In the *Bell Laboratories Record* for May, a full description of the new material is given by A. R. Kemp. It is pointed out how the mixture can be extruded on to the conductor in a continuous sheath of multiple layers free from mechanical defects. The insulated conductor has then only to be drawn through cold water, when it quickly sets into a firm covering sufficiently tough and flexible to resist rough handling in factory or cable ship. The specific conductance of paragutta is only one-thirtieth of that of ordinary cable gutta-percha and its dielectric constant is twenty per cent smaller. It follows that if paragutta had been available to insulate the permalloy-loaded telegraph cable laid five years ago its speed would have been thirty per cent greater. Its revenue-earning capacity would thus have been increased thirty per cent. This is of great importance from the commercial point of view. The expense of failure in a submarine cable is unusually great. Minute defects in its insulation can do far-reaching damage. Very prolonged and elaborate tests were therefore necessary before the cable users and manufacturers were convinced that it was suitable for practical use.

MR. HUTCHINSON'S visit to Africa in 1930, in the company of General Smuts and with the generous assistance of the botanists and forest officers of the districts visited, must have been one of great interest, and especially as Mr. Hutchinson had previously visited some of the same parts in 1928, at a rather different season. The account given in the *Kew Bulletin*, No. 5, 1931, makes good reading from the botanical point of view, and also has the human touches bringing out the joy of seeing new plants and new country, and such difficulties as the drying of paper to keep pace with the press when collecting in an area so little known and with so rich a flora, the problems of motoring on African roads, and camping in lion-inhabited areas. Mr. Hutchinson's two visits should do much to make the flora of South Africa, and especially Rhodesia, better known; certainly the number of new species (five in the genus *Monotes* alone) and the new data bearing on phyto-geographical distribution, which have been collected on this comparatively short trip, point to the scope for such work. Although of very general interest, Mr. Hutchinson's account should be of especial interest to those who have been to any of the parts visited, and from this point of view, members of the British Association who toured through Matopos, Victoria Falls, Zimbabwe, etc., in 1929, will find mentioned many of the plants with which they became acquainted. The publication of further notes on the species collected and of the further volumes of the "Flora of West Tropical Africa" will be anticipated with added interest.

WE have received from the British Drug Houses, Ltd., London, N.1, leaflets describing the preparation, biological standardisation, and uses of certain of their products. Pituitary (posterior lobe) extract is tested, in accordance with the regulations made under the Therapeutic Substances Act, for its oxytocic activity, the strength being expressed in terms of the international unit. In addition, the pressor activity of each batch is determined. The extract finds its chief uses in obstetrics and in the treatment of diabetes insipidus. Radiostol is prepared by irradiation of ergosterol under controlled conditions. Its potency is expressed in terms of the Coward antirachitic unit; as soon as the tests are completed, its activity will be expressed in terms of the unit recently described by the Medical Research Council. Radiostol is a specific in the prevention and treatment of rickets and allied diseases and dental caries. Radio-Malt is a preparation containing Radiostol in combination with a highly active concentrate of vitamin A together with malt extract. It provides vitamins A, B, and D in a palatable form. The tests for vitamin potency are all carried out on rats, the growth response being the criterion for vitamins A and B, and the deposition of calcium at the ends of the long bones of rachitic animals that for vitamin D. The leaflets are illustrated with reproductions of actual tests, and with diagrams of the growth of rats on vitamin-free diets supplemented with Radio-Malt.

The Ministry of Agriculture and Fisheries has published a new *Bulletin*, entitled "Some Diseases of Rabbits". In short clear paragraphs accounts are given of the symptoms of twenty-two diseases to which domestic rabbits are liable, and suggestions are made for treatment. Published by H.M. Stationery Office at the price of *3d.*, this pamphlet should be a useful guide to the many breeders of rabbits for commercial purposes. It should be noted that the Ministry itself carries out at its veterinary laboratory post-mortem examinations and bacteriological work in connexion with rabbits. For a fee of *3s.* a carcass, it is open to rabbit-keepers whose rabbits are dying, or who have other evidence of disease in their stock, to avail themselves of this opportunity for reliable diagnoses. The make-up of the pamphlet is so far in advance of the older publications of H.M. Stationery Office that we dislike pointing to its unbusinesslike publication, but the inefficiency is glaring. In the first place, a note in italics prominently printed upon the 'contents' page states that "The Ministry does not accept responsibility for statements made in the advertisement pages of this publication"—and the only advertisement in the whole pamphlet is one of the Ministry's own publications. In the second place, the most valuable advertising spaces in the pamphlet, the back cover and the inside front cover, are vacant, while there is no indication of the subjects of the thirteen *Bulletins* which have preceded this one. Surely a list of the series cries for one of the vacant pages.

The Report of the National Research Council of the United States for the year ending June 30, 1930, which appeared in the Report of the National Academy of Sciences for the same period, has now been published as a separate pamphlet of 120 pages by the Government Printing Office, Washington. The expenditure of the Council for the year was about £190,000, which was provided mainly by the Rockefeller Foundation, the Carnegie Corporation and Fund, and the Education Board. The issue of comprehensive reports on current knowledge in particular fields has been continued, and several have had to be reprinted—and in general where this has been necessary the opportunity has been taken to revise them, so that they are thoroughly up to date. The research fellowships maintained during the year numbered: in mathematics, physics, and chemistry 63, in biological sciences 41, and in medical sciences 20. The research work of these fellows is supervised by boards which consist of some of the most renowned workers in each particular field. From the total sum expended on fellowships during the year, the average value of a fellowship appears to be £450 per annum, and they are only awarded to candidates of Ph.D standing who have shown marked ability in research.

The Report of the Librarian of Congress, Washington, D.C., for the year ending June 30, 1930, is a volume of more than 400 pages, dealing with the general administration of the Library and with the numerous additions made during the preceding twelve months. The total number of printed books and pamphlets up to June 30 was 4,103,936, of maps and views 1,161,478, and of music (volumes and pieces) 1,062,194. "The most substantial addition to our resources by donation effective during the year", says the report, "was the grant from the Guggenheim fund for the promotion of aeronautics." A part of the fund, 75,000 dollars, was for the endowment of a chair of aeronautics, to which Prof. A. F. Zahm was appointed, while another part was available for the purchase of aeronautical literature. By April 1930 the aeronautical collections comprised no fewer than 9327 volumes and pamphlets, and included the Gaston Tissandier collection, the Samuel Pierpont Langley collection, and other notable collections. "There are, of course," says Prof. Zahm, "many American institutions equipped to furnish ready information in practically the whole range of aeronautics. . . . But for comprehensive, thoroughgoing, systematic research, requiring the greatest range of reference literature, the national Library is, and naturally should be, pre-eminent." Moreover, "Any person, from any place, may examine, within its walls, any book in its possession, and may do this without introduction or credentials".

In vol. 25, part 3, of the *Transactions of the Mining and Geological Institute of India*, December 1930, there is a paper by Mr. C. H. McCale, headed "Suggestions Concerning the Utilisation and Conservation of Indian Coal". The two points especially stressed are the use of coal dust firing and low temperature carbonisation. It was, however, pointed out in the discussion that experience in other countries does not necessarily apply to India, where the conditions are very different from what they are in Europe. In the first place, the demand for power is limited, and therefore the amount of coal dust that can be consumed for the firing of boilers is also relatively small. Furthermore, distances in India are very great; and the transportation of powdered fuel over many thousands of miles is a doubtful proposition unless the fuel is of the highest possible grade, and this is scarcely likely to be the case in India. As regards low temperature carbonisation, although there is a number of companies working processes for this purpose in England, they are not yet commercial propositions, and in India there is the serious additional difficulty of the inability to dispose of the by-products, which are expected to contribute very largely to the commercial success of the undertaking in other countries.

A new aspect of Russian interest in her considerable Arctic territories is expressed in the publication of the periodical entitled *Bulletin of the Arctic Institute of the U.S.S.R.*, of which No. 5 has just appeared. The scope of this bulletin covers all polar regions, north and south, besides giving a more particular account of Russian activities. It also gives a useful bibliography from time to time. The greater part of the *Bulletin* is printed in Russian, but some of the matter is in English. During the present summer, various projects are on foot in Russian Arctic regions, including visits to the meteorological stations in Franz Josef Land and the Kamenev Islands, oceanographical work in the Barents and Kara seas, and geological work in the Chukchee peninsula of north-eastern Siberia.

DR. A. F. JOSEPH has resigned from the deputy directorship of the Imperial Bureau of Soil Science, a post which he has held since the inception of the Bureau in May 1929. He brought to his task a full knowledge of soil problems in different parts of the Empire and a ripe experience in dealing with them; further, his personality helped greatly in smoothing over many of the difficulties of establishment and organisation. The purpose of the Bureau is to supply information to agricultural departments and soil investigators in different parts of the Empire, and the work is complicated by the widely varying problems which have to be attacked. Dr. Joseph has been eminently successful not only in sending out information of the kind that was wanted, but also in putting different workers in touch with one another and so economising time and effort.

THE Proceedings of the first Imperial Horticultural Conference have already been referred in NATURE (Sept. 6, 1930, p. 384). In a foreword to the published account of these proceedings now being issued by the Imperial Bureau of Fruit Production, East Malling, Kent, Sir Robert Greig, chairman of the Executive Council of the Imperial Agricultural Bureaux, remarks that many of the papers presented at this conference proved to be of exceptional technical interest. For this reason it has been decided to print the papers fully; they are being issued in three sections: (1) (issued December 1930) papers on the economic and administrative side of horticulture; (2) (issued February 1931) papers on the application of science to horticulture, (3) papers on the storage of fruit. Part 1 is issued at 1*s*., Part 2 at 2*s*. In Part 2 the papers are grouped under three headings: (1) field experiments, (2) the application of pure science to horticulture, (3) soil and climate as affecting horticulture.

THE Report of the Haffkine Institute for the year 1929 has recently been issued by the acting director, Major L. A. P. Anderson. Plague work necessarily occupies a considerable part of the Institute's activities and of the Report. The demand for Haffkine's plague prophylactic vaccine has been well up to the average, some million and a half doses having been dispatched, and several problems relating to this vaccine have been investigated. A study of the immunising and curative power of various anti-plague serums suggests that a serum prepared in the sheep or ox has greater potency than one prepared in the horse. Inquiries have been made on maternal morbidity and mortality and on stillbirths in Bombay, and on tuberculosis by Dr. Soparkar in this Presidency. In this part of India it would seem that the bovine type of tubercle bacillus plays a negligible part in the causation of this form of tuberculosis. In the Anti-Rabic Department, 685 cases were treated with only 5 deaths, a mortality of 0·73 per cent.

THE Medical Research Council announces that it has awarded Dorothy Temple Cross Fellowships for 1931–32, under the terms of the benefaction in that name for research fellowships in tuberculosis, to Dr. C. A. Birch, senior medical registrar and tutor in the Royal Infirmary, Liverpool, and to Dr. R. L. Vollum, demonstrator in pathology in the University of Oxford. Dr. Birch will study problems of tuberculosis at industrial centres in the United States; and Dr. Vollum will investigate recent developments in methods for the investigation of tuberculosis, in Germany and Austria. The fellowship awarded last year to Lieut. S. M. Burrows, formerly clinical assistant in the Tuberculosis Department, St. Thomas's Hospital, has been renewed for a further year.

THE Ministry of Agriculture and Fisheries announces that the fee charged for the blood test of bacillary white diarrhœa in poultry has been reduced from 3*d*. to 2*d*. This disease is of considerable importance to poultry keepers, and the blood agglutination test is the most practicable means of identifying the carrier hens which transmit the disease through their eggs to the chicks.

MESSRS. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, have just circulated a 'clearance list' of about a thousand second-hand books dealing with zoology, mathematics, chemistry, geology, etc. Most of the prices asked are very low.

IN view of the approaching centenary celebration of Clerk Maxwell, the Cambridge University Press announces a book of essays written to commemorate the event by Sir J. J. Thomson, Dr. A. Einstein, Dr. Max Planck, Sir Joseph Larmor, Sir James Jeans, Sir Ambrose Fleming, Dr. W. Garnett, Sir Richard Glazebrook, and Sir Oliver Lodge. The same publishers will also issue shortly a new work by Mr. T. Whittaker entitled "Prolegomena to a New Metaphysic".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant pathologist at Ancoats Hospital, Manchester—The Gen. Supt. and Secretary, Ancoats Hospital, Manchester (Aug. 12). A graduate assistant in electrical engineering at the Dartford Technical College—The Principal, Technical College, Dartford (Aug. 14). A "Wander" scholar for diseases of children at Westminster Hospital—The Secretary, Westminster Hospital, S.W.1 (Aug. 14). An assistant resident medical officer and resident clinical pathologist at the Manchester Royal Infirmary—The Chairman of the Medical Board, Royal Infirmary, Manchester (Aug. 19). A full-time teacher for mining courses under the Education Department of the County Council of the West Riding of Yorkshire—The Education Officer, County Hall, Wakefield (Sept. 1). A demonstrator in agricultural botany and a demonstrator in agricultural bacteriology in the University of Leeds—The Registrar, University, Leeds (Sept. 1). A full-time assistant master to teach practical metal and woodwork, and engineering subjects at the Victoria Institute Science and Technical School, Worcester—The Secretary for Education, Tudor House, Worcester. A civil engineering assistant for general drawing office and field work at H.M. Dockyard, Portsmouth—The Civil Engineer-in-Chief, Admiralty, S.W.1.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Acromegaly among the old Northmen.

I HAVE read with great interest the description of the Gardarene skull given by Sir Arthur Keith in his "New Discoveries relating to the Antiquity of Man". No pathologist will, I think, doubt that the skull is acromegalic, and this raises the interesting question: Was there anything in the terribly hard life of the Icelandic and Greenland colonists that led to pituitary disorder and so to acromegaly?

There has recently been published a good English translation by Mr. E. R. Eddison of the Egil Saga, and this I think suggests that Egil himself suffered from pituitary disease culminating in definite acromegaly. First as to Egil's personality and appearance. Egil Skallagrimson, the hero of the Saga, lived about a thousand years ago; his activities were not limited to the northlands—Norway and Iceland—for he fought in the battle of Winaheath under Athelstane against Olaf, the half Danish king of Scotland. It is after the victory, as he sat in Athelstane's hall, that the following account of his appearance is given:

"He sat upright, but his head was much bent. Egil was great of face, broad of forehead, with great eye-brows; the nose not long, but marvellous thick; that place wide and long where the moustachios grow: the chin wonderfully broad, and so all about the jaw: thick-necked and great-shouldered beyond the measure of other men: hard-looking and grim-like whensoever he was wroth. He was of goodly growth and taller than any man else: his hair wolf-grey and close of growth, and become early bald" (p. 111).

Here, even in Egil's prime, there is the suggestion of some overgrowth of parts of the face, and the bent neck may be significant. In his old age, that is, between seventy and eighty, he became dull of hearing and blind. There is an episode in which, being sightless, he lies about in front of the fire in the way of the kitchen wenches; later he is warned not to put his feet too near the fire. He was, however, still sufficiently vigorous to kill with his own hands two thralls who had helped him conceal the treasure that Athelstane had given him. After his death, there was an expectation or legend that his bones were particularly long and strong, for later—that is after his bones had been moved—in the church-yard "were found men's bones. They were much greater than other men's bones: men think they know from sayings of old men that they would have been the bones of Egil. There was then Skapti Thorarinson the mass-priest, a wise man. He took up the skull of Egil and set it in the church-yard. The skull was wonderfully great; yet that seemed more beyond all likelihood, how heavy it was. The skull was all wavy-marked on the outside, like a harp-shell. Then would Skapti find out about the thickness of the skull. Took he then a hand-axe, great enough, and swung it with one hand at his hardest and smote with the hammer on the skull and would break it; but there where the blow came it whitened, but dented not nor split. And one may mark from such things, that that skull would be nought easy-scathed before the hewings of small men, while skin and flesh followed it" (p. 222).

Here then we have the skeleton of Egil with especially thick, strong bones and heavy skull with irregular growth of bone on the surface. Two conditions immediately come to mind—acromegaly and osteitis deformans (Paget's disease). Taken alone, the description of the skull might well suggest the latter, but we may be sure that some mention would have been made of the crippling deformity of this disease had Egil suffered from it; moreover, he could scarcely have overcome his two thralls. There remains acromegaly, and here the blindness, and thickness of the skull, seem almost conclusive; indeed, as already indicated, it seems likely that even in his prime Egil had been to a slight degree acromegalic.

At this stage of my hypothesis, I went to the Royal College of Surgeons and, in Sir Arthur Keith's absence, was shown a number of acromegalic skulls by Dr. Beadles. It then appeared that acromegalic skulls could be either thick or thin, and might even be thick in some parts and not especially thick in others. No. 36.1 of the general pathological series is an acromegalic skull with a capacity of 1650 c.c., suggesting some degree of giantism; it is not specially thick, but there is little diploe and the bone is hard. In skull 3861.1 of the special pathological series, that of a modern Roman with no history and with a normal capacity (1500 c.c.), the skull is 2 cm. thick in places; and in another skull, that of a woman (3862.1), the frontal is much thickened. Allowing for a little exaggeration, the Roman skull might, I think, well give something approaching the result obtained on Egil's skull with the hand-axe.

Now, Sir Arthur Keith quotes Prof. Hansen to the effect that several skulls from the same cemetery presented traits resembling those found in the Gardarene skull, "of a similar kind but in a lesser degree" (p. 488). There is, then, evidence of a considerable amount of pituitary disorder among a group of men living a particularly hard life, exposed on their voyages to extremes of cold, to hunger, thirst, and malnutrition, enduring hardships such as only the fittest can have survived, and I would reiterate the question with which I began this letter, but in a more definite form: Was acromegaly—a somewhat rare disease among ourselves—relatively common among the Icelandic colonists and their descendants? If so (and here I would particularly invoke the help of our Scandinavian colleagues), do the circumstances of its occurrence among these adventurous Northlanders offer any hint as to the underlying causes producing alterations in the pituitary gland? C. G. SELIGMAN.

Court Leys, Toot Baldon,
Oxford, July 16.

New Isotopes of Strontium and Barium.

APPLICATION of high resolution to accelerated anode rays has now provided improved mass-spectra of these two elements. Strontium shows a third isotope 87 in addition to those already observed. Results with barium were only obtained with great difficulty. In addition to the main line 138, they indicate the presence of no less than three of the lighter isotopes expected from the chemical atomic weight 137·36. The positions and intensities of these new lines explain the failure to observe them with the older apparatus, for with inadequate resolution their general effect would be indistinguishable from the ordinary penumbra of the strong line 138. Quantitative estimates of relative abundance will be published later. The following are the mass numbers in order of intensity:

Sr	88	86	87	
Ba	138	137	136	135

It will be noticed that Sr^{87} and Ba^{136} form isobaric pairs with rubidium and xenon respectively.

Cavendish Laboratory, Cambridge, July 21.

Age of Certain Gravels in the New Forest Area.

ALTHOUGH the researches of Dr. Longstaff, Mr. H. Bury, Mr. R. A. Smith, and others have thrown much light on Quaternary problems in the New Forest area, a good deal still remains obscure. For sometime past a former pupil of mine, Mr. J. Preston, has been examining the gravel exposures which lie to the east of the Hampshire Avon, and recently we studied together these sites and the various stone tools which have been found. Especially interesting is a pit near Hordle. It lies about 100 ft. above sea-level and opens on the side of a small valley, debouching on the Solent a short distance away. The section in the pit is as follows:

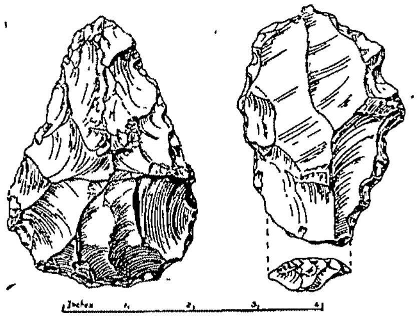

FIG. 1.

(*a*) Surface soil and sub-soil.

(*b*) Thick deposit of coarse gravel, certainly never laid down by river action, and recalling in many ways the main plateau gravel spread which is found all over the New Forest area. This has yielded what appear to be rolled late Chellean and lower Acheulean tools at Stoney Cross and at a site near Picket Post. At the Hordle pit an unrolled *coup de poing* of latish Acheulean type and a but slightly rolled Levallois II flake have been found (Fig. 1).

(*c*) Sand, similar in every way to that found to-day on the beach at Barton.

(*d*) Evenly-bedded gravel, certainly laid down by river action. A slightly rolled example of a late Chellean *coup de poing* has been found, as well as a more rolled specimen of earlier date (Fig. 2).

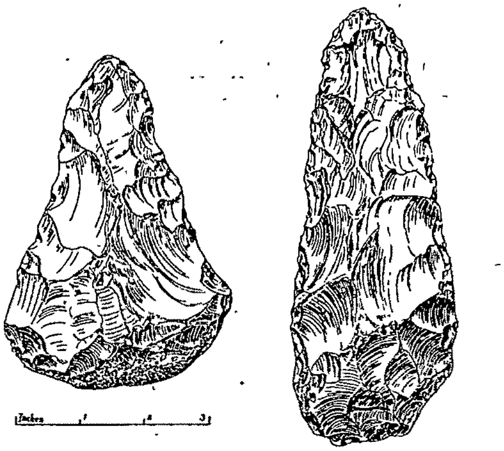

FIG. 2.

Deposit (*c*), taken in conjunction with the general height of the pit above sea-level, suggests that we are dealing with the effects of the same earth movement which formed the 100 ft. raised beach at Brighton, lately discussed before the Geological Society of London by the Rev. J. Fowler. Is it too rash to suggest that the following may have been the sequence of events in this part of Hampshire?

I. Chellean tools were incorporated in fluviatile gravels along the margins of rivers close to the coast-line. The date, judging by the slightly rolled specimen cited in (*d*), must have been towards the end of Chellean times.

II. Submergence of the land to a depth of at least 100 ft.

III. Incorporation of middle Acheulean *coups de poing* and Levallois II flakes in a gravel spread which crept over the whole area, reaching down from what to-day is a height of some 350 ft. at Stoney Cross to nearly sea-level at the Solent. This gravel is to all appearance an outwash gravel, being probably due to glacial conditions beginning to occur to the north of the district. Its age would seem, judging from the archæological data available, to have been late Acheulean. At no very different date, uplift took place and the formation of the existing valleys by the denuding action of the rivers Avon, Stour, and Blackwater. That these valleys, though probably shallower, existed previously is shown by the fact that the gravel spread, mentioned in III, sags a little way down the sides of the modern valleys—clearly, at anyrate in the case of the Avon above Fordingbridge, forming a sort of pseudo-terrace, though always at a high level. At the beginning of the uplift the sea may have helped in the excavation of these deep valleys, and it should always be remembered that the underlying ground is composed of soft Barton Sands.

IV. Formation of low-terrace gravels along the bottoms of the modern valleys. In these a local archæologist (Mr. J. B. Calkin) has found one or two Mousterian tools; mammoth bones have also been found. The age of these gravels is probably Würm. The archæological evidence, therefore, suggests that the uplift just postulated, with the probably simultaneous valley cutting, cannot have occupied any great length of time.

It is obvious that much further work is needed in this interesting area. We can only hope that Preston and other investigators in the district will continue to find further important and interesting material.

Condition of Sparingly Soluble Substances in Gelatine.

IN a recent letter to NATURE,[1] Mr. Nabar and Dr. Desai write: "It is considered that the results obtained from a study of the precipitation of sparingly soluble substances, such as silver chloride, which do not form Liesegang rings in gelatine, should not be applied to explain the condition of sparingly soluble substances, such as silver chromate, which do form Liesegang rings in gelatine. There is a difference in the function of the gelatine in the two cases."

The writers appear to have overlooked some experiments of Bolam and Mackenzie,[2] in which Liesegang rings of silver chloride in gelatin were actually obtained. Moreover, while the observations of Nabar and Desai on the behaviour of the silver electrode in gelatin-silver chromate systems appear to be in agreement with those of Bolam and Mackenzie,[3] their statement with regard to gelatin-silver chloride systems, that "whatever fall in the contact potential is to take place occurs as soon as silver nitrate in gelatine and potassium chloride in gelatine are mixed", is not in accord with the results of Langdon.[4]

The conclusion that the gelatin functions differently in the two cases does not appear to be justified.

T. R. Bolam.

[1] Nature, April 25, 1931, **127**, 628.
[2] *Trans. Far. Soc.*, **22**, 159 ; 1926.
[3] *Trans. Far. Soc.*, **22**, 166, 167 ; 1926.
[4] *Trans. Far. Soc.*, **19**, 285 ; 1923.

With reference to the letter by Mr. G. M. Nabar and Dr. B. N. Desai in Nature of April 25, p. 628, I should like to direct attention to the theory of banded precipitates that I published in various journals as the result of a series of experiments from 1916 to 1922, and summarised in a paper on " Adsorptive Stratification in Gels, V ".[1] In these papers the rôle of the ionic product and the metastable limit is fully discussed.

The authors also appear to be under the impression that silver chloride does not form Liesegang rings in gelatin ; but this is not quite correct. The phenomenon is the same whatever the medium in which the precipitate is formed ; and as I have stated, " No serious attempt to obtain a sufficiently insoluble precipitate in the stratified form has failed. . . . There appears to be no evidence to show that stratification will not occur, provided a precipitate can be obtained in a suitable state of subdivision from solutions of sufficient dilution." Actually the formation of bands of silver chloride in dilute solution in gelatin is recorded by W. M. Fischer,[2] bands of this substance in water in capillary tubes were obtained by Brodersen,[3] and I obtained good bands in U-tubes in agar agar.[4] The formation of banded precipitates of silver chloride, as with any other insoluble substance, for example, silver chromate in agar agar, depends primarily on adjusting the supersaturation produced so that a suitably finely divided precipitate will be obtained.

By the courtesy of the Editor of Nature, I am able to give the following reply to the comments of Drs. Bolam and Bradford on our letter on " Condition of Silver Chromate in Gelatine Hydrolysed and Electro-Dialysed to Different Extents ", published in Nature of April 25, 1931, p. 628.

Drs. Bolam and Mackenzie[1] have not given any experiments in which silver chloride rings in gelatine were obtained in the absence of silver chromate. In our experiments, the contact potential of the silver electrode reached its final value as soon as the solutions of silver nitrate in gelatine and potassium chloride in gelatine were mixed, a result which does not agree with the observations of Langdon.[2] Using the same sample of gelatine, it was, however, found that with silver chromate the fall in the contact potential of the silver electrode was gradual. The contact potential measurements show that, in our experiments, silver chloride in gelatine was not in ionic condition, but that silver chromate was. We hold that, in the first case, gelatine acts as a protective colloid, and in the second case, as an inhibiting agent ; and that it is the inhibitive power of gelatine which is responsible for the formation of Liesegang rings.

We agree with Dr. Bradford that serious attempts to obtain a sufficiently insoluble precipitate in the stratified form will prove successful. We also believe that just as bands of silver chloride in gelatine can be obtained by taking the former substance in sufficient dilution, the bands of the same substance in gelatine can be obtained even in slightly stronger solutions, provided the *p*H of gelatine is decreased sufficiently. We have found experimentally that the inhibitive power of gelatine towards silver chromate can be altered considerably even by slight changes in its *p*H value. We are at present studying the effect of changing *p*H of gelatine on its efficiency in giving banded precipitates (rings) of different sparingly soluble substances.

All the points raised in the communications of Drs. Bolam and Bradford are dealt with in detail in a paper which will be sent shortly for publication.

Oxidation Reduction Potential of Complex Iron Compounds in Yeast.

When an alkaline extract of yeast is saturated with ammonium sulphate there is precipitated, with the protein, cytochrome ' C ' and a complex iron compound giving no visible spectrum. The latter can be separated from the proteins slowly by ultra-filtration. It remains in solution when the protein, with the cytochrome ' C ', is precipitated by trichloracetic acid.

This iron compound is of interest because its oxidation potential (E_0, referred to the normal hydrogen electrode, = +0·02 at *p*H 7·1) lies very close to that at which the spectrum of cytochrome ' C ' appears and disappears—a potential near which a variety of aerobic organisms appear to function. In quite low concentration it prevents the hydrogen electrode from giving correct values in buffered solutions—a property which makes it seem likely that it can act as a catalyst.

That the iron is complexly bound and not in the form of simple ferrous or ferric ions is shown by the fact that even in a large excess of such a buffer as a concentrated borate–tartrate mixture, the oxidation reduction potential of this compound lies about 0·25 volt above that of ferric chloride added to the buffer. The iron of the compound does not react with sulphocyanide when oxidised, but does react slowly with *aà* dipyrridyl when reduced.

An attempt to isolate the compound is now in progress. Because its oxidation potential is close to that of cytochrome ' C ', and because it is apt to accompany the latter in attempts to obtain the pure pigment, there is some danger of confusing the effects and properties of the two substances.

Measurement of Ultra-Violet Radiation.

We are interested in the photographic method of recording the ultra-violet light of the sky, which has been described by Dr. J. R. Ashworth.[1]

With reference to the criticisms of Dr. Cunliffe[2] the objection to the step-wedge does not appear to be important ; it is probable that the logarithmic ' law ' is approximately correct and in any case the wedge can be calibrated. It is, of course, well known that the photographic effect of an exposure is not a simple function of the time integral of the intensity and that an intermittent exposure does not give the same effect as a continuous exposure for the same total time. It is pertinent, however, to point out that the physiological response to radiation is somewhat analogous and that a photographic measurement may, therefore, be particularly valuable.

A further point for consideration appears to be the quality of the radiation recorded. It is generally agreed that little benefit is derived by man from ultra-violet radiation of wave-length greater than about 3200 A. and we note that Dr. Ashworth's filter transmits radiation between 3400 and 3700 A. Possibly the thin silver film transmitting radiation of wave-length 3130 A., described two years ago by Mr. Lamplough in a paper to the Royal Society of Arts, could advantageously be substituted.

The methylene blue method developed by Messrs. Webster, Hill and Eidinow shares with Dr. Ashworth's method the disadvantage of response to the longer wave-lengths; in addition, the sensitivity appears to be affected by temperature changes.

The Forbidden Lines in the High Frequency Discharge of Mercury, Cadmium, and Zinc.

IN addition to the observed results of the intensity modification of spectra in the high frequency discharge in mercury, we have found the forbidden lines $1S - 2p_1$ of mercury and $1S - 2p_1$ and $1S - 2p_3$ of cadmium with moderate intensities. The quartz tube was 15 cm. long and 2 cm. in diameter, and the pressure of vapours was kept at about 0·001 mm. mercury. The spectra were excited with external electrodes by a 10-metre oscillator, and observed in it, end on. Heating the tube caused the discharge to become brighter, and a remarkable intensity modification was observed in mercury, as is seen from the reproduction of the microphotometric records of the spectra at 70° C. and at room temperature (Fig. 1). It can be seen that the effects of a slight rise of temperature are: (1) the vapour emits only the series lines, while spark lines appear at room temperature; (2) the intensities of the series lines decrease quite regularly with the increase of the number of the members; (3) the forbidden line $1S - 2p_1$ enhances more than the neighbouring triplet lines $2p_2 - 12d$ and $2p_2 - 13d$.

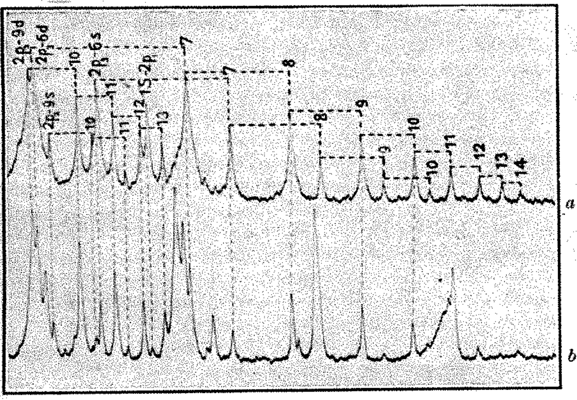

FIG. 1.—Photometric curves of the spectra of mercury, (a) at 70° C., (b) at room temperature.

In cadmium, in consequence of the strong concentration of atoms excited in D-levels, it was possible to observe 12 members in the singlet diffuse series and 8 members in the p-D intercombination lines. Intercombination lines which begin on the triplet levels are less affected, and the pp'-combinations which are emitted strongly in the arc are lacking in this discharge. In zinc, the singlet sharp series are strengthened and it was possible to observe 10 members, and the triplet series was slightly affected. It is to be regretted that we could not find the forbidden line in this vapour.

According to W. Hanle's work on the excitation function (*Anregungsfunktion*) of the spectral lines of helium, neon, and mercury, the maximum of the excitation function of the triplet levels is sharp in form and lies at about 10 volts, while that of the singlet levels is flat and at about 30 or more volts higher than the former. If it is assumed that electrons which have velocities of about 20 volts predominated in our exciting condition more than that of lower volts, the strengthening and weakening of the lines will be explained with reference to the observation of W. Hanle. As the pressure of vapours is very low, the interatomic field due to ionised or excited atoms will certainly be very weak, and this will also be a favourable condition for the emission of the forbidden lines. In the case of mercury, a slight rise of temperature favours the condition, probably in consequence of the increase of the frequencies of the collisions between atoms and electrons, the number of slower electrons becoming greater.

A full account of these experimental results will shortly be published elsewhere.

Part-Absorption in X-Rays.

IN connexion with the experiments of one of us (B. R.) on the part-absorption in X-rays,[1] the results of other workers on the same subject are conflicting. While Cork,[2] Lindsay,[3] and Van der Tuuk[4] report negative results, Bhargava and Mukherjee[5] confirm our results so far as the part-absorption lines are concerned. It seems to us that the conflicting results obtained by different authors are simply due to the thickness of the absorption screens used by them in their experiments.

In the first experiment, described in NATURE of May 17, 1930, the copper $K\alpha$-radiation was allowed to pass through carbon powder lightly pressed in a slit of about half a millimetre thickness. The modified line appeared to be very feeble. Later on, the carbon powder was replaced by goldbeater's skin, which contains nitrogen and oxygen in addition to carbon. By trial, it was found that five pieces of goldbeater's skin when pressed on the slit of the spectrograph produce modified lines beautifully on the photographic plates.[6] We have further found that the increase in thickness of the absorption screen does not necessarily increase the intensity of the modified lines; or rather, on the contrary, if the absorption screen is too thick, the modified lines disappear completely.

Further investigation on the variation of intensity with the different thickness of the absorption screen is still in progress. It appears that the negative results of Cork, Lindsay, and Van der Tuuk may be due to the large thickness of the absorption screens used by them. In this connexion it may be mentioned that Bhargava and Mukherjee obtained the modified line of carbon by passing the copper $K\alpha$-radiation through only four pieces of ordinary black paper used for wrapping the photographic plate. Later on they obtained a line of type $\mathrm{Ag}K\alpha - \mathrm{Ni}K_{\mathrm{abs.}}$ (Prof. M. N. Saha, in a private communication, has written to us that Messrs. Bhargava and Mukherjee have also found a line of the type $\mathrm{Ag}K\alpha - \mathrm{Cu}K_{\mathrm{abs.}}$)

Cork (l.c.) reports a line $\mathrm{Cu}K\alpha - \mathrm{Be}K\alpha$ by passing copper $K\alpha$-radiation through Lindeman glass, which contains beryllium (0·9 per cent) among other constituents. As we have found in our experiments in carbon screen, Cork also finds that the intensity of this line does not increase by placing a beryllium screen in the path of the incident radiation. Further, non-appearance of any line modified by boron (which is another constituent of the Lindeman glass) might be due to the higher percentage of boron in the glass.

Lindsay (l.c.) has suggested that sometimes false bands appear on the photographic plate, due to the imperfection of the crystals. In our experiments the modified lines were obtained with both fixed and rotating crystals on a large number of plates. Generally, the crystal was rotated by hand about 2° on each side of the expected line. The rate of rotation of the crystal was 0·1° in every five minutes. In some plates this rate was varied. The modified line appeared as usual in every case, and thus the question of rotation of the plate does not affect our results so far as the modified lines are concerned.

The intensity estimate[7] is wrong, owing to an unfortunate mistake in comparing the blackness with a wrong plate. We have re-estimated the intensity of the modified lines and it appears to be of the order of 1 in 1000 (or even less) in comparison with the parent line. Agfa-Röntgen film is found to be more suitable for this type of investigation than ordinary plates.

Fine Structure of Raman Lines in Liquids.

I HAVE investigated the Raman spectra of several liquids with a spectrograph of high dispersion specially built for this purpose. The spectrograph was placed in a thermostat in order to allow very long exposures without losing anything in definition, owing to variation in the refractive index of the glass prisms.

With this apparatus I have observed, for the first time, so far as I know, the isotope effect in Raman spectra. I have succeeded in measuring the isotope effect in carbon tetrachloride and in stannic chloride, among other substances. The observation confirms the analysis of the infra-red absorption spectra of this substance proposed by Cl. Schaefer.[1] The work will appear in detail in the *Zeitschrift für Physik*.

I have also obtained beautiful Raman spectra of a number of different liquids. The plates show that the Raman lines have a characteristic structure, resembling unresolved vibration-rotation bands. This confirms the suggestion recently proposed by A. Kastler[2] that the rotations of the molecules in liquids are quantised.

Concentrated ammonia liquor gives a strong Raman band which is due to the NH_3-molecule. This band shows a distinct rotation structure. It is composed of a strong, unresolved Q-branch, surrounded on both sides by a succession of lines, of which the strongest have a spacing corresponding to the formula

$$\nu = 3317{\cdot}4 \pm 19{\cdot}87 \times J.$$

Further, there is a number of weaker lines with an average spacing of 9·7 cm.$^{-1}$. The rotation structure of the band consists obviously of a strong Q-branch and two positive branches, a strong R- and a weaker S-branch. Of the negative branches, the P-branch is rather strong, while the O-branch seems to be very weak. The intensity of the lines has a maximum at $J = 4$–5, as in the infra-red absorption spectrum.

The Raman band of water has a very complicated structure which, on addition of an electrolyte, becomes more distinct. In collaboration with Mr. Hugo Fredholm, I am extending systematic work in this direction.

I might finally mention a result which implies the possibility of a partial rotation of a molecule, as suggested by Bonino and Cella[3] in the case of pinene. Toluene, $C_6H_5 . CH_3$, gives a number of Raman lines of which two, commonly ascribed to the vibration C – H, show rotation structure. The Raman band $\nu_0 = 3056{\cdot}3$ cm.$^{-1}$, has the simplest structure. It is composed of a strong, unresolved Q-branch, a strong negative and a weaker positive branch, corresponding to the formula

$$\nu = 3056{\cdot}3 \pm 7{\cdot}0 \times J.$$

If these branches are interpreted as P- and R-branches, the spacing leads to a value for the moment of inertia, $I = 7{\cdot}9 \times 10^{-40}$ gm. cm.^{2}, which is in excellent agreement with the value to be expected for a rotating methyl group. Further details will be given elsewhere.

Occurrence of *Lithothamnion* in the South Indian Cretaceous.

WHILE examining some micro-sections of rocks from the Trichinopoly Cretaceous (South India), I have recognised the presence of *Lithothamnion* in several of the sections. This form has not been reported before from this area; and except for a passing reference by Hayden[1] to the occurrence of *Lithothamnion* in certain Cretaceous (?) beds of the Kampa system in Tibet, I believe the present find is the first of its kind to be reported from the Cretaceous of any part of India.

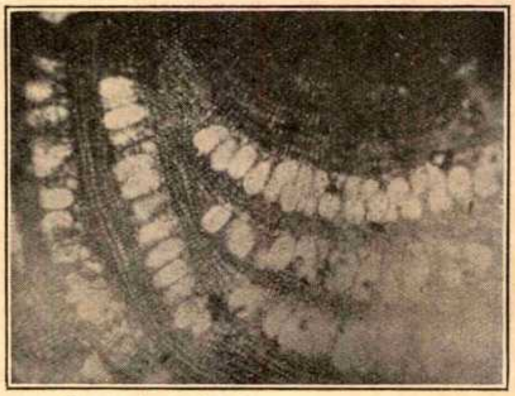

FIG. 1.—Archæolithothamnion sp ? × about 25.

In view of the great interest attached to this discovery, some of the sections were sent to Dr. Julius Pia, of the Natural History Museum, Vienna, and he has identified the form as *Archæolithothamnion* (Fig. 1), and some of the sections appear to be identical with *A. torulosum*, which he has figured in his chapter on Algæ in Hirmer's "Handbuch der Paläobotanik". The form has been recognised in quite a large number of sections, and it is certain that a detailed study of these will reveal not only more than one species of *Lithothamnion* but also the presence of several other types of Algæ. As regards the age and locality of these rocks now under study, they all belong to the Niniyur stage, which is the youngest subdivision of the Trichinopoly Cretaceous and corresponds to the Danian of the European stratigraphical scale.

The Energy of Horizontal Atmospheric Motion.

With reference to my note on atmospheric structure in Nature of June 27, it should be remarked that for any part of a horizontal field of isobars at which the velocity of the air is in geostrophic accord with the gradient the energy of a layer of air of uniform thickness contained within a square lying between a pair of consecutive isobars is the same for any part of the field, due allowance being made for variation of density and latitude. Hence the energy of the field can be estimated by counting the number of squares which are accommodated in the field.

The proof of this assertion is as follows:

Let the isobars be drawn for intervals of b millibars; let the distance between a pair of consecutive isobars be l, and let h be the thickness of the layer for which the geostrophic equation holds.

Let V be the velocity of the air, ρ its density, ϕ its latitude, ω the earth's angular velocity.

Then the mass of the layer of air within the square of which the side is l is $\rho l^2 h$, and the velocity V is $\frac{b}{2l\omega\rho}\operatorname{cosec}\phi$.

Hence the energy is $\frac{1}{8}\frac{hb^2}{\rho\omega^2}\operatorname{cosec}^2\phi$.

It is consequently the same for every square, whatever its size may be, which lies between isobars with the same pressure interval. If we take as our unit of energy $\frac{1}{8}\frac{hb^2}{\omega^2}$ and denote it by N, the energy for any square within the layer is $\frac{\operatorname{cosec}^2\phi}{\rho}N$. If any portion of the field be made up of such squares and their number n counted, the energy of that portion of the layer, expressed in terms of the unit N, is $n\operatorname{cosec}^2\phi/\rho$.

The value of the unit N for a layer 100 m. thick with a pressure interval of 2 mb. is about 26,000 kilowatt-hours, worth £100 at a penny per B.T.U.; or with ρ 1000 gm./m.^{3} (nearly normal at 2 km. height) the energy is 35 million kw.-hr. in latitude 60°, 104 million kw.-hr. in latitude 30°.

The number n can be obtained by inscribing successive circles tangent to the pair of isobars and to each other and counting their centres.

When isobars are curved, computation is still possible, but the formula requires modification.

This reasoning enables us to compute the energy of the horizontal motion of a 100-metre layer, shown on the maps of isobars at various levels in the troposphere. The energy between 30° N. and 60° N. clearly increases with height up to 8000 metres at least.

Napier Shaw.

July 4.

Jubilee Celebrations of the Society of Chemical Industry.

Please allow me to amend that portion of the account of the jubilee celebrations of the Society of Chemical Industry, published in Nature for July 25 (p. 157), which refers to the development of the chemical autoclave as illustrated by "a series of drawings and exhibits by the National Physical Laboratory". The actual origin of these illustrations and specimens is entirely otherwise. The drawings were made by Mr. H. Tongue, principal technical assistant of the Chemical Research Laboratory, Teddington. The collection of autoclaves included representative examples of various types constructed at my suggestion over a period of fifteen years, first at the Finsbury Technical College, then in the University of Birmingham, and recently in the Chemical Research Laboratory, the cost of production having been met in all cases by the Department of Scientific and Industrial Research.

The account also refers to "reduction products of fluorine compounds"; the substances exhibited were reduction products derived from the hydrocarbon, fluorene.

Full particulars regarding the exhibits from the Chemical Research Laboratory are given in a very serviceable handbook to the Exhibition, published by the Chemical Engineering group of the Society of Chemical Industry.

About forty members and guests of the Society of Chemical Industry visited both the Chemical Research Laboratory and also the Departments of Metallurgy and Metrology in the National Physical Laboratory, this being the first occasion on which the former institution has been inspected by a large party of visitors.

G. T. Morgan.

Chemical Research Laboratory,
Teddington, Middlesex.

Control of Prickly Pear by the Cochineal Insect.

As a result of a long series of tests carried out in Australia under the Commonwealth Prickly Pear Board, it was ascertained that the cochineal insect, *Dactylopius tomentosus*, could only live on certain species of *Opuntia*, among which was *O. dillenii*. As this species was reported to be a pest in India and Ceylon, I was authorised to offer strains of this cochineal bred in the laboratory free from parasites to the Government entomologists of those countries. The offer was accepted by Ceylon, and the insects were successfully established there in 1924 or 1925. In India, the offer was considered at a conference of the entomologists of the various provinces, and it was decided not to accept it, on the ground that prickly pear was largely used for hedges, and that, where it threatened to become a pest, it could easily be eradicated, as abundant cheap labour was available.

It appears from his letter in Nature of July 18, p. 117, that Mr. C. T. Jacob has introduced the insect from Ceylon to South India "to destroy clumps of *O. dillenii* in which dangerous snakes were harbouring around business premises".

The last sentence of the leading article in the same issue of Nature, p. 86, "that more may be involved in the thoughtless importation of strange animals than the importer can possibly conceive", seems appropriate to this instance.

Research Items.

Age of the Giant Tortoises of Galapagos.—In 1928 a number of giant tortoises, all belonging to the species *Testudo vicina*, were brought from the Galapagos Islands by the New York Zoological Society and deposited at different stations where their development might be watched. At the stations the rate of growth differed, the three individuals in Arizona showing only a 66 per cent increase, while in Florida and Texas more than 200 per cent increases were attained (C. H. Townsend, *Zoologica*, vol. 9, p. 459; June 1931). The author states that the differences are traceable chiefly to climate and treatment, but it is obvious that size is also an important factor, smaller specimens on the whole showing the larger growth percentage. The age of the giant tortoises while comparatively young seems to be traceable in the striations of the horny plates of the carapace. Where age is definitely known up to twelve or even twenty years, the striations agree in number with the years, but in larger and older individuals the ridges tend to flatten out and become illegible. The author states that the common notion that large Galapagos tortoises must be of extremely old age is unwarranted, though he adds that the real length of life is unknown. Under favourable conditions they reach a large size in a few years, when the rate of growth becomes slow. Nevertheless, there are records of giant tortoises from both Galapagos and Aldabra which lived under observation in tropical climates for more than 150 years, dying upon their removal to cold climates.

Hairs and Wools.—Begun as a study in the significance of human and other hair in the detection of crime, Dr. John Glaister's researches have led him to make a comparative investigation of the hairs of a vast number of mammals. The results appear as an imposing quarto volume of 187 pp. and 145 plates, "A Study of Hairs and Wools", published by the Faculty of Medicine of the Egyptian University, where the author is professor of forensic medicine. The author concludes that a critical examination of hair will always reveal the mammalian order or suborder to which it belongs, in a very large number of instances will betray the family, and in many cases the species. If it be a human hair, in an appreciable number of cases it is distinctive of sex, in most cases it can be allocated to its site on the body, and in "a very approximate manner" may decide the age of the possessor, as very young, adolescent, adult, or aged, provided a number of hairs are available. Such identifications can only be made by an expert, however, and that after a laborious comparison with a large series of authentically identified human and animal hairs. It is a pity that in the reproduction by half-tone process the finer markings of the hair surfaces are often lost, for obviously the blocks have been made from a very fine series of photographs; but we are thankful to have this handsome and costly work, the publication of which was made possible by the generosity of the Egyptian Government.

Echinostomes from Rats.—Rats trapped in the city of Manila for routine bubonic plague inspection, are also examined for intestinal and other parasites. A. Tubangui (*Philippine Jour. Sci.*, 44, March 1931) reports that, of 109 rats, one brown rat harboured in its small intestine twenty-one specimens of an echinostome fluke that is believed to be identical with the human intestinal fluke *Euparyphium ilocanum*, and another brown rat yielded more than a hundred specimens of an apparently new species of the same genus. *E. ilocanum* was first recovered by Garrison (1908) from the stools of Filipino (Ilocano) prisoners in Manila, and was afterwards recorded from natives of the neighbouring province of Zambales. Its presence in a Manila rat may mean that this human parasite has a wider field of distribution than has formerly been supposed, and that rats are a factor in its dissemination. Descriptions and figures of the two flukes are given. The number of species of flukes now recorded from the brown rat is fourteen.

Polymorphic Characters in Rotifers influenced by Feeding.—Polymorphic characters expressed in the number of lateral spines occur in the rotifer *Brachionus pala*, which has four anterior and two posterior spines, while the variety *amphiceros* has two lateral spines in addition, which vary in size in different individuals. The effects of temperature and feeding upon the two forms has been tested by Kenzo Kikuchi (*Jour. Fac. Sci., Imp. Univ. Tokyo*, Sect. 4, vol. 2, p. 163; 1931). It was found that change of temperature had scarcely any effect upon the spines of *Brachionus pala*, but when it was fed with the green alga *Scenedesmus*, lateral spines characteristic of the variety *amphiceros* were produced. The progeny of the variety fed on *Polytoma*, however, had no lateral spines. So also when examples of *B. amphiceros* were fed upon *Polytoma* they lost their lateral spines, but when the progeny of this deficient form were fed with *Scenedesmus* they grew spines and became *amphiceros*.

Tetraploid and Triploid Petunias.—A tetraploid *Petunia* with twenty-eight chromosomes has been described by Dr. Kostoff. It was larger and more succulent, with larger flowers and broader leaves; it also developed faster than the diploid, but was self-sterile. The offspring from pollinating this plant with the diploid is now described by D. Kostoff and James Kendall (*Jour. of Genetics*, vol. 24, No. 2). Sixteen tetraploid plants (with twenty-eight chromosomes) were produced, as well as two hypotetraploids with twenty-seven chromosomes, one triploid (twenty-one chromosomes) and one hypotriploid with twenty chromosomes. The meiotic chromosomes of the tetraploid hybrids were usually found associated in rings or chains of four during diakinesis. Their reduction processes were almost regular and there were only 2 per cent of abortive pollen grains, the plants setting good seed when selfed. In the original tetraploid mother-plant, however, there were many meiotic irregularities and only half the pollen was good. The tetraploid hybrids are believed to have arisen either from both male nuclei uniting with the diploid egg, or from the union of the latter with a diploid male nucleus from a pollen dyad. The triploids and hypotriploids showed many meiotic irregularities and were self-sterile, but could be pollinated successfully by the tetraploids.

Building of the Northern Appalachians.—From Alabama to New York the Palæozoic formations of the Appalachian geosyncline were folded into mountains shortly after the beginning of the Permian, and it has been commonly assumed that this orogeny continued from New Jersey to Newfoundland, notwithstanding the clear demonstration by the pioneer geologists of Canada that the northern section of the Appalachians was folded in the main during the Devonian, with minor deformations in the late Ordovician and late Carboniferous. Prof. C. Schuchert has discussed the facts afresh in the *Bull. Geol. Soc.*

Amer., 41, pp. 701-724, 1930. He finds evidence for a four-fold deformation, progressing from the interior oceanward: (*a*) an arch-making movement at the close of the Cambrian which separated the St. Lawrence geosyncline into two seaways; (*b*) the Taconic isoclinal folding and overthrusting, with nappes, towards the end of the Ordovician; (*c*) the Acadian disturbance of Devonian time accompanied by the initiation of the Gulf of St. Lawrence; and (*d*) the Appalachian revolution of the Permian, which elevated the Maritime Provinces and refolded the Acadian geosyncline. Schuchert considers the crossing of earlier by later folds to begin in Nova Scotia, whereas Bailey placed the beginning of the crossing in south-east Maine.

Deep-Focus Earthquakes.—The occurrence of earthquakes of abnormal focal depth is a question on which opinion is not in complete agreement. The late Prof. H. H. Turner had put forward this hypothesis, but there is evidence both for and against it. The problem has been reinvestigated by F. J. Scrase, in a paper in the July number of the *Proceedings of the Royal Society*, from the point of view of reflection of the waves. In general, a number of supplementary reflected waves should occur, and if the focus is sufficiently deep, they should produce definite separate phases on the records; from an examination of a considerable body of data, it is found that these can be recognised and that the times of transit are in reasonable agreement with the calculated times. A corresponding feebleness of the surface waves which has been observed in many earthquakes also lends support to the deep-focus hypothesis. The results of the investigation favour the idea that the initial phase of an earthquake is a direct compressional wave and is not generated by reflection of a distortional wave (see also NATURE, 127, p. 486, Mar. 28, 1931).

Collision between Organic Molecules and Surfaces.—It is now possible with modern vacuum technique to allow beams of molecules to impinge on a surface, and to collect the molecules leaving the surface, under conditions such that no interaction occurs between individual molecules in either the incident or the reflected beam. The July number of the *Proceedings of the Royal Society* contains an account of an investigation of this type by F. O. Rice and H. T. Byck, in which the molecular beams contained acetone or dimethyl mercury. These were allowed to impinge upon targets of platinum, tantalum, and tungsten, which could be heated, and an analysis was made of the products leaving the surfaces. The results of most significance were obtained with platinum. No decomposition whatever of the compounds could be detected as a result of their collisions with the metal, although the temperature of the metals was well above that required for decomposition under ordinary conditions, and it is concluded that the molecules must have left the surface very soon after reaching it: that is, that both adsorption and trapping in irregularities on the surface was of no importance. With tungsten and tantalum, some decomposition into hydrogen and carbon monoxide, and possibly other products, was detected, above 1085° for the former metal and 1400° for the latter, but in these cases surface reactions occurred with the formation of carbides.

Nuclear Moments.—A review of the work which has been done upon the rotation of the nuclei of atoms has been published by R. de L. Kronig and S. Frisch in the issue of the *Physikalische Zeitschrift* for June 15. In line spectra this manifests itself by the appearance of a hyperfine structure, which requires special sources and instruments of high resolving power for its study. It can be described formally by the introduction of a new quantum number, and has its origin physically in the various modes of quantised magnetic coupling which can occur between the nucleus and the valence electrons. The nuclei of isotopes may differ in their spin properties, and so introduce a fresh complication into the hyperfine structure. With molecular spectra the nuclear spin may control the intensities of alternate lines in certain bands, in some cases alternate lines being absent. The magnitude of the nuclear spin can be deduced from the intensity data. Although hyperfine structure was discovered by Michelson, it is only in recent years that any systematic study of it has been made, and Prof. Kronig's list of elements for which the nuclear spins have been investigated includes only thirty-one.

Wave-Mechanical Models of Atoms.—Some pictorial representations of hydrogen-like atoms which are published by H. E. White in the first June number of the *Physical Review* are of interest as giving probably as definite an idea as is possible of atomic structure on modern theory. They were obtained by utilising the fact that the Schrodinger equation for a hydrogen atom can be separated into three equations, the solution of one of which leads to an expression for the probability that the electron will be at various distances from the nucleus, and of another to the probability for various inclinations of the line joining the electron and nucleus to an external magnetic axis. A spindle was turned to the shape of the radial 'probability-density', and was photographed whilst rotating about the 'magnetic' axis, the angle between the axis of the spindle and the magnetic axis being changed at a variable rate to represent the corresponding part of the solution of the wave-equation. The resulting photographs are a set of symmetrical patterns, one for each atomic state, and are shown in the paper in white on a black ground. To obtain the closed *s*-states a slightly different procedure was followed. The pictures show clearly the approximate agreement between the wave-mechanical representation and the region swept out by a precessing orbit on the Bohr theory, and equally well, the existence of lobes in some of the wave-mechanical models which are not called for at all in the early quantum theory.

The Arc Spectrum of Zirconium.—An analysis of the arc spectrum of zirconium, the outcome of some ten years of work upon this element, is described by Dr. and Mrs. Kiess in the United States Bureau of Standards *Journal of Research* for April. The lines and terms of this spectrum are numerous, but more than twelve hundred of the sixteen hundred lines which have been measured have been classified and the terms of the spectrum assigned to definite configurations of the atom by the aid of Hund's theory. The spectrum has many features of interest. Several pairs of related states of the atom have almost the same energy, with the result that pronounced perturbations of the individual pairs occur, and cause both abnormalities in the intensities of lines which arise from transitions from these terms and Zeeman patterns for them which depart from their simple theoretical values. Lines of this spectrum also appear in the Fraunhofer solar spectrum, but, as has been found with the spectrum of singly ionised zirconium, certain of these have to be ascribed to transitions in the atom which are theoretically possible, and of which the magnitude can be predicted from other lines, but they are of small intensity or even absent with laboratory sources. The resonance lines and *raies ultimes* have been identified, and the ionisation potential of the neutral atom shown to be 6·92 volts.

Anti-Neuritic Vitamin.—Previous methods for the isolation of anti-neuritic vitamin have yielded only very small quantities of material which is probably still far from chemically pure. In the June number of the *Journal of the American Chemical Society*, Seidell and Birckner, of the National Institute of Health, Washington, describe experiments on the isolation of the vitamin from yeast, the process involving four stages. An 'activated solid' is first prepared by adsorption on fuller's earth of the filtered yeast extract made at 80°. Extraction of the solid is now made by agitating it violently for five minutes in 0·4–0·5 *n*NaOH and centrifuging. The clear liquid is rapidly acidified to *p*H 3·0 with sulphuric acid. On evaporation under reduced pressure to one-tenth, a brown solid separates, which has been shown to be very rich in the thermostable growth factor (B_2 or G) required as a supplement to anti-neuritic vitamin for normal growth. The clear liquid is cooled for deposition of sodium sulphate, and inorganic salts, impurities, etc., are precipitated with alcohol to approximately 50 per cent alcohol in the solution. This alcoholic solution contains the anti-neuritic (B_1) vitamin, but only about 15 to 20 per cent of that originally present in the yeast. The solution is distilled down to small volume, centrifuged, and benzoylated with sodium carbonate and benzoyl chloride, extracted with chloroform, and the aqueous layer poured slowly into 10–15 vols. of acetone. The precipitate is extracted with a mixture of propyl alcohol and concentrated hydrochloric acid, distilled down and poured into acetone. The precipitated solid is dissolved in methyl alcohol and added dropwise to a large volume of acetone. The white voluminous flaky precipitate is washed with acetone and dried in a vacuum. It is curative in 0·03 mgm. doses by the Smith rat method, or about one-fourth greater than the crystals obtained by Jansen and Donath in 1927.

Aceto-acetic Ester Condensation.—Since the discovery by Geuther in 1863 that aceto-acetic ester, $CH_3COCH_2COOC_2H_5$, is formed by the action of sodium on ethyl acetate there has been much discussion as to whether the metal itself is responsible for the condensation (Michael's theory), or whether the active agent is sodium ethoxide formed from traces of alcohol in the ester or from other side reactions (Claisen's theory). It was found by Michael that ethyl acetate from which all traces of alcohol have been removed reacts with sodium as readily as the ordinary ester, but it is possible, of course, that some alcohol might be produced by a side reaction. It has also been shown by Snell and McElvain that acetic and propionic esters are unique in not giving the corresponding acyloins when treated with sodium in presence of excess of ester, and a study of the reaction mechanism should therefore be confined to them. In the June number of the *Journal of the American Chemical Society*, these authors state that they have made a careful study of the reaction between sodium and ethyl acetate in which the amounts of aceto-acetic ester, alcohol and hydrogen produced have been determined. Similar determinations were made with sodium ethoxide as condensing agent, and the results obtained appear to constitute strong evidence in favour of Claisen's theory. The amount of alcohol found in the mixture when sodium is used is approximately the sum of that produced by the aceto-acetic ester condensation and that resulting from the reduction of the ester by the sodium used in the reaction. The action of the sodium thus appears to be the generation, by reduction of the ester, of sodium ethoxide, which is the real condensing agent. In contradiction to earlier investigators, but in agreement with the recent experiments of Kutz and Adkins, it was found that sodium ethoxide produces practically the same amount of condensation, and just as readily as metallic sodium does.

Astronomical Topics.

Nagata's Comet, 1931 *b*.—This proves to be the brightest comet observed for several years. The following orbit and ephemeris have been circulated from the U.A.I. Bureau at Copenhagen. They are by Mr. Berman:

T	1931 June 15·140 U.T.	
ω	324° 58′	1931·0
Ω	191 8	
i	41 24	
$\log q$	0·03342	

EPHEMERIS FOR 0^h U.T.

	R.A.	N. Decl.
Aug. 7	12^h 0^m 24^s	10° 16′
11	12 14 56	10 9
15	12 28 56	9 58

The light on July 26 and Aug. 7 is 0·9 and 0·6 of that at discovery. The comet should be looked for in the evening twilight.

The two following positions of Nagata's comet are from photographs by Nicholson and Moore at Mt. Wilson:

U.T.	R.A. 1931·0.	N. Decl.
July 18·1792	10^h 40^m $44{\cdot}7^s$	9° 51′ 3″
19·1861	10 45 6·0	9 54 47

The comet had a tail 4° long (*Harvard Card*, No. 161).

Changes of the Corona in the Sunspot Cycle.—It has for a long time been recognised that the type of the corona varies with the sunspot cycle, having polar streamers at spot-maximum and equatorial extensions with delicate 'polar plumes' at minimum. Dr. W. J. S. Lockyer reopens the subject and extends his study up to 1930, in *Mon. Not. Roy. Ast. Soc.* for May. He introduces statistics of prominences, and his discussion indicates that the correlation between prominences and the corona is much closer than between spots and the corona; and further, that the latitudes of prominences and of the coronal streamers are very closely associated. Prominences attain much higher latitudes than spots, and even reach the poles of the sun at the times of spot-maximum. Dr. Lockyer notes that the corona of the 1926 eclipse was of maximum type, although it was nearly two years before spot-maximum; but the prominences had already reached high solar latitudes. He refers to the corona of 1908, which, when the photographs were first published, appeared to have little connexion with the prominences; but it was afterwards found that the orientation marked on the photographs was wrong.

The research also indicates that the latitudes of prominences and coronal streamers are somewhat higher during increasing than during decreasing sunspot activity; in other words, maximum prominence latitude precedes maximum sunspot activity. Reference is also made to the 'coronal arches' that appear above prominences in many eclipse photographs. They afford further evidence of the close connexion between prominences and corona.

Dr. Lockyer anticipates that the 1932 corona will be nearly of minimum type; the sunspot minimum is expected to be about 1934.

Centenary Meeting of the British Association.

PROGRAMMES OF SECTIONS.

SECTION A (MATHEMATICAL AND PHYSICAL SCIENCES).

A CENTENARY meeting in London necessarily envisages a programme which differs in many details from the programme of a provincial meeting. The occasion is one for a certain amount of stocktaking, and nothing could more clearly demonstrate the remarkable progress of the physical sciences during the period that has elapsed since the jubilee meeting than a comparison of the topics that interest the Section to-day with those of half a century ago. The Section anticipates a specially large gathering of guests from foreign lands and from the overseas dominions, and the programme naturally reflects in some measure the interests of a number of these distinguished visitors.

The president of the Section, Sir J. J. Thomson, proposes to discuss the increase in the facilities for education and for research in physics that the last fifty years have seen.

A large number of discussions has been arranged, and perhaps that of widest general interest is a discussion which bears the not unambitious title of "Evolution of the Universe". This discussion will be held in the Great Hall of the University of London, and will be opened by Sir James Jeans. General Smuts (president of the Association), Prof. E. A. Milne, Sir Arthur Eddington, Prof. W. de Sitter, Sir Oliver Lodge, Prof. R. A. Millikan, and the Bishop of Birmingham will contribute. Of more immediate technical interest are the discussions on geophysical prospecting, with special reference to instruments, to be opened by Prof. A. S. Eve, and on the unit of atomic weight, when Dr. F. W. Aston, in opening the discussion, will review critically some of the more suitable suggestions for such a unit, for example, those of the proton, the neutral hydrogen atom, one quarter of the α-particle, one quarter of the neutral helium atom, one sixteenth of the neutral oxygen atom. He will advance arguments in favour of (*a*) retaining the present chemical scale, (*b*) adopting one sixteenth of the neutral oxygen atom as standard.

Sir Napier Shaw will present a communication on meteorology through the century, and papers will be read before the main section by Profs. R. W. Wood, G. P. Thomson, J. C. McLennan, P. Zeeman, and others.

The mathematical subsection presents a comprehensive and technical programme. Titles such as "Asymptotic Partition Formulæ" and "Tesseral Matrices" are *φωνᾶντα συνετοῖσιν*, but even those whose interest in such subjects is passing small may find attractive Prof. J. B. S. Haldane's paper on some "Mathematical Problems of the Biologist".

The subsection of cosmical physics is organising a discussion on magnetic storms, which will be opened by Prof. S. Chapman. A programme of very wide interest has been prepared, which includes papers ranging over such diverse subjects as lightning, Nova Pictoris, stratified clouds, deep focus earthquakes, and radio research in the empire.

Sectional excursions have been arranged, through the kindness of the directors of these institutions, to Greenwich Observatory, to the National Physical Laboratory, to the G.E.C. Research Laboratories, to a Nelson Line steamship, and to Kew and Slough.

SECTION B (CHEMISTRY).

The coincidence of the Faraday Centenary celebration with that of the British Association is particularly happy so far as the Chemistry Section is concerned. Faraday's discoveries in many branches of chemistry and physics were so numerous and so fundamental that it is difficult to determine which is the most important from all points of view, and his eminence as the pioneer in physical chemistry will probably be emphasised in Sir Harold Hartley's presidential address, "Michael Faraday and the Theory of Electrolytic Conduction". The remainder of the programme will take the form of four discussions, and the first of these will immediately follow the presidential address. Profs. P. Debye (Leipzig), N. J. Bjerrum and J. N. Brønsted (Copenhagen), K. Fajans (Munich), J. C. Philip, S. R. Milner, and Sir Harold Hartley have promised to speak on "The Influence of the Medium on the Properties of Electrolytes".

The morning and afternoon of Friday, Sept. 25, will be devoted to the chemistry of the vitamins and related substances, which was also discussed at a recent meeting of the Royal Society. Those taking part in the discussion on the chemistry of vitamin A and the carotinoids include Profs. P. Karrer (Zurich), H. von Euler (Stockholm), R. Kuhn (Heidelberg), J. C. Drummond and I. M. Heilbron, and Drs. R. A. Morton and T. Moore. In connexion with the chemistry of vitamin B and related problems, the speakers are Profs. B. C. P. Jansen (Amsterdam) and R. A. Peters, while the chemistry of vitamin D and related sterols will be discussed by Profs. A. Windaus (Gottingen) and I. M. Heilbron, and Drs. R. Bourdillon and O. Rosenheim. Sir F. Gowland Hopkins will introduce the discussion, which will be summed up by Prof. R. Robinson.

On Sept. 28, the Section will hold a symposium on the British fuel problem, and on the following day the final discussion will be on the structure of simple molecules. This will be introduced by Prof. P. Debye, who will also quote the evidence from X-ray measurements. The other speakers will be—Prof. J. E. Lennard-Jones on evidence from molecular spectra, Mr. R. H. Fowler on the quantum mechanical theory of valency, Prof. V. Henri (Marseilles) on predissociation and the structure of some special molecules, Prof. F. G. Donnan and Mr. C. N. Hinshelwood.

Special exhibits will be on view during the meeting; those already arranged are by Dr. R. C. Menzies (illustrating the chemistry of thallium), Prof. C. S. Gibson (illustrating some recent investigations of the chemistry of gold), and Prof. H. V. A. Briscoe (illustrating the chemistry of rhenium).

SECTION C (GEOLOGY).

The proceedings of Section C (Geology) will open with the address of the president, Prof. J. W. Gregory, in which he will review to some extent the last hundred years of geology. This will be followed by an account of the geology of the London district by Mr. H. Dewey, of the Geological Survey, and Dr. S. W. Wooldridge, and two papers concerned with that area.

The principal business of the Section will be the discussion of certain phases of the science that are of interest at the present time. The first, on "The Evidence of Palæontology with Regard to Evolution", will be opened by Sir Arthur Keith; other speakers will include Dr. R. Broom, of South Africa, Dr. W. D. Lang, Profs. Hawkins, Swinnerton, Trueman, and D. M. S. Watson. The pronouncements of the opener have been so provocative of late that this discussion may be of the greatest interest.

Prof. O. T. Jones will introduce a subject of more importance perhaps to the practising geologist, "On

Earth Movements in Relation to Stratigraphy". In this discussion Prof. E. B. Bailey and Mr. J. Weir, will consider "Submarine Faults as Boundaries of Facies". Prof. H. A. Brouwer, of Holland, and Dr. E. O. Ulrich, of the United States, will carry the discussion far beyond the limits of the British Isles.

The other subjects are of greater economic interest and will show how the purely scientific and the practical are connected. As the Section meets in the Royal School of Mines, it is very appropriate that Prof. G. C. Cullis should introduce there the subject of "The Genesis of Ores in Relation to Petrographic Processes", and here it is probable that its economic importance will be stressed. Prof. P. Niggli, of Zurich, and other petrologists can be expected, however, to explore thoroughly its relation to petrogenesis.

The place that oil and oil products have in the world to-day should make the fourth and last discussion, on "The Genesis of Oil Pools in the Sedimentary Cycle", of the widest interest. The first speaker will be Prof. V. C. Illing, and representatives of the great producing companies have promised to contribute.

As these discussions will necessarily occupy most of the time available, other papers will be given before appropriate sub-sections. Of these, one by Dr. C. A. Matley should be of great historic interest, for in his account of the Harlech Dome the author will deal fully with Lapworth's work on that area. Dr. Matley has also arranged to have an exhibit illustrative of Lapworth's maps and papers in the Imperial College of Science.

A full programme of excursions has been arranged for the week of the meeting, and during the week preceding a party will visit East Anglia under the guidance of Profs. Boswell and Kendall.

Section D (Zoology).

The programme this year of Section D (Zoology) is on quite novel lines, as there are no papers upon individual topics. Each of the six mornings is being devoted to special subjects, and is occupied by a discussion, a symposium, or a mixture of the two. Prof. E. B. Poulton's presidential address, "A Hundred Years of Evolution", opens the sectional meetings, and the rest of that morning will be filled by a series of short papers on particular aspects of the evolution question, followed by a short general discussion. The authors of the short papers are Prof. Julian Huxley, Prof. H. Fairfield Osborn, Dr. F. A. Dixey, and Mr. E. B. Ford.

On the following day the topic is vertebrate embryology. Prof. E. W. MacBride is opening this discussion and Dr. J. H. Woodger and Mr. C. H. Waddington are to follow him, so we may look forward with certainty to a lively general discussion of the subject. The Saturday morning is to be devoted to the population problem. The names of Profs. Carr-Saunders, Crew, J. B. S. Haldane, Hogben, Huxley, and MacBride, Dr. R. A. Fisher, and Mr. J. R. Baker, are a guarantee of a stimulating three hours' discussion.

Monday is the systematists' day, but the subject, "Classification with Reference to Phylogeny and Convergence", upon which Dr. Tate Regan (opener) and Drs. F. A. Bather, W. D. Lang, Hugh Scott, and John Stephenson have promised to speak, should provoke a ready response from other members of the Section in the open discussion towards the end of the morning. The Tuesday programme concerns variation and genetics, the particular subjects to be dealt with being induced mutations, local races, study of lineages, and the mathematical side of evolution, by Prof. J. W. Heslop Harrison, Drs. W. R. Thompson, W. H. Thorpe, and O. W. Richards, Prof. D. M. S. Watson, and Prof. J. B. S. Haldane respectively. Finally, on Wednesday the applied side of zoology is to the fore. Prof. W. Garstang and Drs. A. Bowman and E. S. Russell are discussing the various aspects of the 'over-fishing problem'; and then Drs. A. D. Imms, Ll. Lloyd, C. B. Williams, J. C. F. Fryer, and P. A. Buxton are contributing to a symposium on insects and human welfare.

In the afternoons, visits have been arranged to most, if not all, the places of special interest to zoologists within easy reach of South Kensington; and on the Sunday there is to be a whole-day excursion to Tring and Whipsnade.

Section E (Geography).

The programme arranged for this Section includes a series of topics representative of the field of geographical studies at the present day. In addition, it is fitting that on this occasion the evolution of the subject as indicated by successive British Association meetings should be traced, and very appropriately such a review is to be given by Dr. H. R. Mill, who has had such a long connexion with the Section.

A former president, Sir Halford Mackinder, will again preside over the Section, and his address will be on "The Human Habitat". The Section will also have the advantage of its president's leadership in the Saturday excursion which has been arranged to the south-east coast, an area rich in its illustrations of so many phases of our historical geography.

A subject of special interest at the present day, that of the establishment of national parks, will be considered by Dr. Vaughan Cornish, with particular reference to "The National Park of Northumberland, a Shrine for Hadrian's Wall". The London area will be dealt with in two papers, of which the first, by Dr. Wooldridge, will analyse the physical setting, while the second, by Mrs. Ormsby, will consider various aspects of the evolution of the Metropolis, with particular reference to the growth of its population.

Papers of imperial interest will form an important element at the centenary meeting, and the Section is fortunate in having guests from both Australia and South Africa. Dr. Fenner, of Adelaide, is to deal with some problems of South Australia, while Prof. J. H. Wellington, of Johannesburg, is to review the important question of land utilisation in South Africa. A paper which is certain to arouse considerable interest has also been promised by Prof. Griffith Taylor—whose name is inevitably associated with that of Australia—under the title of "The Geographer's Aid in Nation-Planning". Some recent agricultural developments in the Empire will be considered by Sir John Russell, while Lord Lugard will deal with the profoundly significant problems of tropical Africa in an address which he is to give on Africa in transition.

Among the foreign guests of Section E will be Prof. W. Werenskiold, of Oslo, who is to give a résumé of his researches into the variations of glaciers and of climate in Norway.

Finally, a day is to be devoted to a symposium on geographical problems of the earth's crust. The opening paper in this series will be by Mr. A. R. Hinks, and others who have promised to contribute include Prof. J. W. Gregory, Prof. A. Holmes, and Dr. G. C. Simpson.

Section F (Economic Science and Statistics).

A varied programme, in which the main feature is a number of papers dealing with important economic problems of current interest, has been arranged for Section F (Economic Science and

Statistics). The president of the Section is Prof. Edwin Cannan, and he has selected for his presidential address the subject of "Internationalism in Economic Theory". Mr. J. H. Morris will discuss the important but difficult problem of "The Rationalisation of the Cotton Industry". During the past few years, the difficulties of primary producers in all parts of the world have been very prominent, and in this connexion the papers of Mr. J. W. F. Rowe on "The Artificial Control of Raw Material Supplies" and of Mr. R. R. Enfield on "The World's Wheat Situation" are of special interest. Another interesting session should be that in which Mr. Maurice Dobb is to read a paper on "Some Economic Problems connected with the Five-Year Plan in Russia". Prof. J. H. Jones is to give a lecture on "Wages, Prices, and Employment", and this should lead to an important discussion of the much-debated question of the interrelation of these factors and of the causes of the present grave unemployment problem.

A new feature of the Section's activities is the formation of a group dealing with industrial co-operation. In connexion with other sections, a wide range of papers and discussions has been arranged to deal with these industrial problems, including means of co-operation between industry and educational institutions in promoting the training of managers; the physiology and psychology of work; the utility of trade barometers, and patents and the protection of scientific discovery.

Section H (Anthropology).

Section H (Anthropology) will profit very much from the centenary meeting, since it is attracting many field workers from overseas. Following upon the presidential address by Prof. A. Radcliffe-Brown, of Sydney, a session will be devoted to papers from field workers in Oceania. Field workers from South Africa, including Dr. R. Broom, will also speak.

Special interest is attached to a morning given up to reports of work in the Mediterranean region carried out by Misses Caton-Thompson and Gardner, Miss D. A. E. Garrod, and Mr. W. A. Heurtley. Problems of British archæology, including accounts of work at Avebury, of Upper Palæolithic finds in north Lincolnshire, and of Early Iron Age finds in Monmouthshire, will also be discussed. Among papers by distinguished foreign guests are the Huxley Memorial Lecture by Dr. Thilenius, suggestions for studies of ethnic pathology by Dr. Suk, of Brno, an account of Neanderthal man in Italy by Dr. Sergio Sergi, and a discussion of the possibilities of determining the geological age of fossil man by comparison with the teeth of contemporaneous Proboscidea, by Prof. Henry Fairfield Osborn. A lecture to which the public are invited will be given at 5.30 P.M. on Monday evening, Sept. 28, by Prof. Elliot Smith, on the now famous Peking man.

An almost untouched subject, the psychological origins of law, will be opened up by His Honour Judge Dowdall, and will, it is hoped, lead to further research into this important aspect of man's social activity. Social phenomena among various primitive peoples will be discussed by field workers, including agriculture and land ownership among the Hopi, the economic factor in primitive life, birth dances, the magical significance of tattoo designs, and a general paper on the social organisation of the Nilotes by Prof. C. G. and Mrs. Seligman. Prof. Seligman will also deal with heredity in modern human hybrids. The complex problem of the relation between Canaanites and Hyksos will be raised by the veteran field worker and archæologist, Sir Flinders Petrie, while Nineveh and its origins will be discussed by Dr. Campbell Thompson, who has carried out three seasons' work there.

An interesting feature will be exhibitions arranged by courtesy of the Director at the Wellcome Museum, including a collection of crania from South Africa brought over by Dr. Broom, and photographs of native South African life taken by Mr. Duggan-Cronin. The afternoons will be devoted to visiting the museums and private collections in which London is so rich, and the Section is deeply grateful for the special facilities which curators and keepers are arranging for its members.

Section I (Physiology).

The first morning's proceedings in Section I (Physiology) are to be devoted to a discussion on the "Physiological Basis of Sensation", which will be opened by Prof. E. D. Adrian, Foulerton professor of the Royal Society. He will be followed by (among others) Dr. C. S. Myers, Sir J. Herbert Parsons, and Prof. Frank Allen, of Winnipeg.

On Friday morning (Sept. 25), Prof. E. P. Cathcart, of Glasgow, is to speak on the relation of rations for children to those of the 'standard' adult man, Prof. A. V. Hill is describing the lost place of lactic acid in the study of muscular contraction, and Prof. Charles Heymans is speaking on the control of the circulation, to which his researches have contributed so much. At the end of the morning, Prof. J. Barcroft will discuss the physiological problems entailed by such an expedition as that of climbing various Himalayan summits. It will be interesting to hear the opinions of Mr. E. N. Odell, who was on the 1924 Everest expedition, and of Dr. Raymond Greene, of the 1931 Kamet climb, on Prof. Barcroft's opinion that climbing is dependent almost entirely on an appropriately designed apparatus for the supply of oxygen.

Dr. H. H. Dale is using his presidential address to open a discussion on the "Biological Nature of Filtrable Viruses", while the rest of Monday morning (Sept. 28) is to be devoted to a discussion on the same subject. Among those speaking are Dr. T. M. Rivers, of the Rockefeller Institute, New York, Dr. Alexander, of Onderstepoort, and Mr. J. E. Barnard.

The morning of Sept. 29, which is the last business meeting of the Section, is devoted to a discussion on "Methods and Problems of Resuscitation". The opening address will be given by Sir Edward Sharpey Schafer, and among those who will follow are Prof. Yandell Henderson, of Yale, Dr. J. S. Haldane, Dr. C. K. Drinker, of Harvard, Sir Bernard Spilsbury, and Sir Francis Shipway. This is probably one of the problems in which applied physiological methods have been of most interest and value in practical work.

The afternoon and evening arrangements of the Section include visits to the Royal College of Physicians and to the Wellcome Historical Museum.

Section J (Psychology).

Section J (Psychology) is fortunate in having as its president this year Dr. C. S. Myers, for he was largely responsible for its formation as a subsection of I (Physiology) in 1913 and as a separate section in 1921, and is one of the pioneers in the development of experimental psychology and its application to the problems of industry. The subject of his address will be "The Nature of Mind".

The programme for the Section is a strong and varied one; most of the past presidents of the Section—Profs. Bartlett, Brown, Drever, Pear, and Valentine—will figure in it. Among the distinguished foreign guests who will contribute papers are Prof. Kohler of Berlin, Prof. Piéron of Paris, and Dr. Frank Allen of Toronto. Prof. Köhler will speak on "Recognition and Reproduction", Prof. Piéron on "The

Theoretical and Practical Aspects of Intelligence", and Dr. Allen on "The Function of Induction in Colour Vision".

An intra-sectional discussion has been arranged on "Mental Defect", at which papers will be read by Dr. E. O. Lewis on "The Social Aspects of Mental Deficiency", by Prof. F. A. E. Crew on "The Genetic Background of Mental Defect", by Dr. R. G. Gordon and Dr. Norman on "Some Psychological Experiments of Different Types of Mental Defectives", and by Dr. F. C. Shrubsall on "The Classification of the Mentally Defective and the Relative Frequency of Different Types".

The organising committee of the Section decided to restrict the meetings to the morning sessions, hence, as the programme is very full, two sets of papers will run concurrently on two mornings. Visits have been arranged to the psychological laboratories of King's, University, and Bedford Colleges, to the Tudor Lodge Child Guidance Clinic, Islington, the Jewish Child Guidance Clinic, the Bethlem Royal Hospital, and the National Institute of Industrial Psychology.

SECTION L (EDUCATIONAL SCIENCE).

Sir Charles Grant Robertson has chosen for his presidential address to Section L (Educational Science) a subject in full accord with the special nature of the centenary meetings of the British Association, namely, "Educational Development: 1831 and 1931: A Centenary Retrospect and a Forecast". The address is to be delivered in the Great Hall of the University on the morning of Sept. 24. Dr. E. Deller will follow with a paper on "London as a Pioneer in University Education", and in the discussion afterwards, Sir Frank Heath, Sir Robert Blair, Sir Philip Hartog, Sir William Beveridge, Sir John Gilbert, and the Rev. Scott Lidgett will take part.

On the second morning two subjects, Imperial in nature, will be considered: "The Establishment of a Central Institute for Imperial Education" and "The Education of Backward Peoples". Lord Eustace Percy, Prof. F. Clarke, and Mr. F. H. C. Butler will give papers on the former, and Sir Michael Sadler, Dr. Maxwell Garnet, Sir Percy Nunn, and Major A. G. Church will speak in the discussion. Papers on the latter subject will be read by Mr. S. Rivers Smith, Major H. A. Harman, and Dr. A. R. Paterson, and in the discussion the Hon. Hugh A. Wyndham, Lord Raglan, Mr. A. Victor Murray, Mr. C. W. Hobley, and Miss M. F. Perham will speak.

The next session is to be devoted largely to problems connected with school clinics and child guidance. Three papers are to be given: Dr. G. A. Auden will deal with "The Maladjusted Child", Dr. W. Moodie will follow with "Environmental Factors in Maladjustment", and Dr. A. Macrae will give the third paper on "Psychological Examination as an Aid to Vocational Adjustment". Dr. C. W. Kimmins, Dr. Emanuel Miller, Dr. J. R. Rees, Dr. C. L. C. Burns, Dr. R. G. Gordon, and Mr. D. T. John will also state their views. The session will close with a paper and discussion on "Eugenics in Education". Prof. R. Ruggles Gates is reading the paper, and Prof. Julian S. Huxley, Prof. E. W. MacBride, and Sir Arthur Thomson will take part in the discussion.

At the final session "School Broadcasting" will be dealt with by Mr. Frank Roscoe and Lord Eustace Percy. There will be an appropriate demonstration, and Sir Walford Davies will open the discussion and Miss Mary Somerville will answer questions. A paper on "Adult Education Broadcasting", by Prof. Winifred Cullis, will follow, and Mr. C. A. Siepman will take part in the discussion and questioning.

The reports of three special committees will be presented during the meeting. Sir Percy Nunn and Mr. G. W. Olive will report on "General Science in Schools with special reference to Biology"; Sir John Russell and Mr. C. E. Browne will present a report on "Education for Life Overseas"; and Sir Richard Gregory and Mr. J. L. Holland will deal with the report of the Committee on Educational and Documentary Films.

SECTION M (AGRICULTURE).

Sir John Russell's presidential address to Section M (Agriculture) on "The Changing Outlook in Agriculture" gives the keynote for the whole sectional programme. Each session treats a single aspect of agriculture and selects representative products or problems to illustrate how the application of science has influenced the development of practice, how current problems are being attacked, and in what directions developments may be expected.

The first two sessions are devoted to crop production, the next three to animal production, animal health, and the utilisation of animal products, and the final session to the economic aspects of agriculture in Great Britain and the Empire.

The application of genetics to the improvements of varieties of cereals and to fodder plants will be considered by Dr. E. S. Beaven and Prof. R. G. Stapledon, who, whilst emphasising the importance of breeding from the material indigenous to any area, will direct attention to the danger that the present movement to pedigree strains may defeat its purpose by the development of an international trade in pedigree seed without reference to its merits for the particular purpose required. On the animal side, Prof. F. A. E. Crew will raise the question whether attempts at animal improvement in newer areas by the importation of specimens of improved European breeds possess any advantage over the less favoured one of selection towards a desired type amongst the animals already existing in any particular locality.

Dr. S. G. Barker will examine the scientific and economic aspects of methods of sheep breeding to produce wool suitable for specific manufacturing processes. On the veterinary side, Sir Arnold Thieler will carry his well-known work in South Africa a step further by his demonstrations that 'stiffsickness' may be identified with true rickets or osteomalacia, and that it is caused by a deficiency not of calcium but of phosphorus.

Dr. D. J. Hissink will give an account of the reclamation of the Zuider Zee, whereby the cultivated area of Holland will be increased by one-tenth; he will discuss especially the way in which the original infertile magnesium and sodium clay is converted into a fertile calcium clay by the removal of sodium salts by drainage. Industrial crops are represented by surveys of the present position of the production and research on rubber and cotton, and for the utilisation of animal products, milk and the cold storage of meat will be treated.

Probably the widest interest will be aroused by the discussion on the economic aspects of agriculture, which will begin with reviews of the present position and outlook for cereals by Sir A. Humphries, and for meat by Sir William Haldane. Possible changes in the organisation of farming will then be considered by Sir Daniel Hall, who will discuss the units for farming, and Mr. C. S. Orwin, who will put forward the claims for a higher degree of specialisation.

Excursions have been arranged to the Rothamsted Experimental Station, the laboratories and farm of Imperial Chemical Industries at Jealott's Hill, and the Dairy Research Institute at Reading.

Birthdays and Research Centres.

Aug. 13, 1872.—Prof. Richard Willstatter, For.Mem.R.S., professor of chemistry in the University of Munich.

In recent years I have been occupied chiefly with such different things as silicic acid, that is true monosilicic acid, and with the enzymes of leucocytes. With regard to these, I began with studying the protein-splitting enzymes, trypsin and kathepsin, their occurrence and behaviour in the colourless blood-cells of herbivores and carnivores. At the present time I am engaged in analysing the glycogen-splitting enzyme of leucocytes. Concerning the peculiarities of amylase, it is surprising how much information can be obtained from observations with blood-cells. In the muscle, where the metabolism of carbohydrates is being studied so thoroughly, things must be so much more intricate.

In connexion with my problem I should like to raise a question. Is it to be taken for granted that glands are producing enzymes, or are they disintegrating the blood-cells and selecting and storing the enzymes ?

Aug. 14, 1861.—Sir Richard Threlfall, G.B.E., F.R.S., chairman of the Fuel Research Board.

I regret that for the past year my health has not permitted me to live continuously in England, and consequently the amount of work I have been able to do has been but small. My main occupation has been the investigation of the decolorising power of charcoal which has been activated by partial combustion in sulphur vapour, and I am looking forward to continuing this work as soon as my health permits me to do so.

I have also had on hand for several years the study of a gravity balance (Threlfall and Pollock, *Phil. Trans.*, 1899), with the assistance of Mr. Dawson. This instrument gave very promising results in Australia so far back as 1898, but there are indications that, after more than thirty years, some slipping is beginning to take place at the joints where quartz is soldered to metal. There is, however, another possibility which I am now investigating, but in the meantime the behaviour of the instrument has become unsatisfactory.

I am also engaged in attempting to bring out a new edition of a small book on " Laboratory Arts " which I published during the 'nineties, and which now, of course, requires very copious revision. The proposed changes are mostly in MS., but I am unfortunately short of the kind of assistance required to enable me to get it through the press.

Aug. 15, 1871.—Prof. G. Elliot Smith, F.R.S., professor of anatomy in University College, London.

The results achieved by recent research in comparative neurology now for the first time open the way for a comprehensive synthesis of our knowledge of the brain, and suggest the possibility of new and fruitful methods of studying the factors which were responsible for the attainment of the growing powers of skill and understanding in vertebrates and the making of the mind in man. If this great scheme of research is to be realised, the most urgent need is the correlation of the information acquired by comparative anatomy and physiology, by clinical investigation and experimental psychology, as well as by palæontology and anthropology, with properly critical attention to considerations of phylogeny and chronology, so as to define the means whereby the drastic revolutions which occurred in the central nervous system—and, in fact, the whole organism—when each of the different classes of vertebrates came into being, made possible new modes of locomotion and new possibilities of behaviour, and how the refinement of sensory discrimination eventually made the acquisition of higher degrees of skill attainable.

My aim at the present time is the study of the means whereby these general biological principles found expression in the process of conferring upon man's ancestors the higher powers of understanding and skill which transformed them into men.

Societies and Academies.

Paris.

Academy of Sciences, June 15.—**Adolphe Lindenbaum** : Regulated ensembles.—**Francesco Severi** : Biharmonic functions and the theory of analytical functions of two complex variables.—**Gaston Julia** : Conformal representation of multiple associated areas.—**Gr. C. Moisil** : The use of generalised vector potentials in the integration of a class of partial differential equations.—**R. Gosse** : Equations $s=f(x, y, z, p, q)$ which admit of an invariant of the second order.—**G. Cerf** : The characters of systems in involution of partial differential equations.—**S. Mazurkiewicz** : The problem of Lusin.—**F. E. Myard** : Closed chains with five rotoid couples deformable at the first degree of freedom.—**E. Chausse** and **J. Baubiac** : The secondary vortices produced below an obstacle immersed in a liquid.—**Fernand Baldet** : The Raffety bands and the spectra of comets. The radiations from the nuclei of comets cannot be identified with the Raffety bands given by the flame of an oxyacetylene blowpipe.—**Ch. Racine** : Contribution to the study of the static problem in the theory of relativity.—**L. Goldstein** : The application of quantic mechanics to chemical kinetics. **Maurice Robert** : Application of the oxymetal rectifier to the measurements of the maximum potential difference.—**Stanislas Teszner** : Recording mobile waves with a modified Dufour cathode ray oscillograph.—**Louis Leprince-Ringuet** : Relation between the path of a rapid proton in air and the ionisation which it produces. Application to the study of the artificial disintegration of the elements.—**F. Margand** : The damping of the oscillations of polyphase synchronised machines in the theory of two reactions.—**Georges Fournier** : The translation of light intensities into sound intensities. By means of the apparatus described, by listening at a telephone a blind person can distinguish the position of a window or source of light, the surface occupied on a table by a sheet of white paper, and other phenomena of light.—**P. Waguet**, **A. Stampa**, and **J. Dourgnon** : The rôle of irregularities of the profile of reflectors for motor car projectors and their photographic control.—**Daniel Chalonge** : The variations of the energy distribution in the continuous spectrum of molecular hydrogen.—**Henri Grenat** : The identification of the Raffety spectrum.—**Marcel Laporte** : The chemical reactions of ionised gases. The synthesis of nitric acid.—**Cazaud** : The influence of the magnitude of the micrographic grain on the resistance to fatigue of mild steel. The effects of cold-hardening, of annealing, and of overheating.—**Marcel Godchot** and **Mlle. G. Cauquil** : The viscosities, surface tensions, and parachors of some cyclo-hydrocarbons.—**A. Portevin** and **A. Sanfourche** : The attack of the common metals by solutions of phosphoric acid. Twelve metals were submitted to the attack of solutions of phosphoric acid of different origin and of varying concentrations. The results are given in a diagram.—**L. Bert** : The action of 1, 3-dichloropropene on the sodium phenols.—**P. Carré** and **P. Mauclère** : The transformation of the polyatomic alcohols into mono- and polychlorhydrins by means of thionyl chloride.—**E. Calvet**: Velocities and heats of saponification of the amides. The heats of saponification of the amides of the fatty series vary but little from one term to the next, but the saponification velocities vary rapidly, especially for the first terms.—**Lespieau** and **Reginald L. Wakeman**: The preparation of the trimethylene hydrocarbons: 1-methyl-2-propylcyclopropane. Starting with β-brompropaldehyde, methylpropyltrimethylene has been prepared free from its ethylene isomer, as shown by its Raman spectrum.—**Raymond Paul**: Some derivatives of 1, 4, 5-pentane triol.—**Paul Gaubert**: The diffraction rings produced by spherolites with helicoidal structure.—**Robert Lami**: The saline heterogeneity of rock pools on the sea coast during rain.—**A. Guilliermond**: New researches on the microchemical characters and the mode of cytological formation of the anthocyanin pigments.—**Henri Coupin**: An unrecognised factor of the momentary variation of plants.—**A. Ch. Hollande** and **Mme. G. Hollande**: Cytological study of the different stages of the Eberth bacillus (*Bacterium typhi*).—**Charles Richet, Jr.**, and **Jean Dublineau**: The effects of the puncture of the fourth ventricle on the combustion of protein materials.—**Fernand Mercier** and **Léon J. Mercier**: A new sparteine salt, neutral sparteine valerianate.—**G. Champetier**: The formation of the alkali celluloses.—**P. Carneiro** and **W. Kopaczewski**: The nature and specificity of antigens. The experiments described lead to the conclusion that immunity appears to be an electrocapillary phenomenon.—**A. Trillat**: Experiment on infection by air. The case of chicken cholera. The practical conclusion from the results obtained by the author is that chicken cholera can be transmitted by the air, especially confined air: hence poultry houses should be well ventilated in order to free them from the moisture accompanying the gaseous products of respiration.—**C. Levaditi, P. Ravaut, P. Lépine**, and **Mlle. R. Schoen**: The affinity of a virus isolated from inguinal granulomatosis (Nicolas and Favre's disease) for the lymphatic system of the ape.

CRACOW.

Polish Academy of Science and Letters, March 20.—**G. Bouligand**: An application of the paratangent to a problem of superficial measurement.—**Mlle. M. Charpentier**: A topological problem arising out of the theory of the differential equations $\dot{y}=f(x, y)$.—**S. K. Zaremba**: The trend of the integrals of an ordinary differential equation of the first order in the neighbourhood of the singular integral supposed to exist.—**L. Infeld**: The constitution of the wave associated with free electrons.—**W. Kessel**: The complexity of the resonance spectrum of selenium vapour.—**M. Kamieński**: Researches concerning the movement of the periodic comet, Wolf I. Part 12. Disturbances of the path of the comet by Uranus from 1884 to 1919.—**M. Centnerszwer** and **J. Szper**: The electrolysis of fused alkaline nitrites. The products are nitrogen and alkaline oxide at the cathode, nitrate and a mixture of NO_2 and NO at the anode.—**K. Dziewoński** and **J. Moszew**: The synthesis of diethyl-α-α-acenaphthyl-diketone (αα-dipropionylacenaphthene).—**K. Dziewoński** and **J. Spirer**: Syntheses and transformations of two diketones: αα- and ββ-derivatives of acenaphthene.—**K. Konior**: The tectonic of the border of the Carpathians between Biala and Andrychów.—**St. Macko**: Two peat bogs in the neighbourhood of Zamość, studied by means of pollen analysis.—**St. Maziarski**: Genetic studies of the genus *Ægilops*. The morphology and cytology of interspecific hybrids.—**J. Jarocki**: The Mycetozoa of Czarna Hora (Polish Eastern Carpathians).—**J. Zaćwilichowski**: The innervation and the sensorial organs of the wings in insects (2).—**F. Górski**: The action of weak electric currents on chlorophyll assimilation in *Elodea canadensis*.—**M. Konopacki**: The micromorphology of the eggs and embryos of the frog (*Rana fusca*) submitted to centrifugation.

April 13.—**G. Bouligand**: The regular and positive solutions in the whole plane of the equation $\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}=u$.—**A. Rosenblatt**: The movements adjacent to plane radial movements of incompressible viscous fluids.—**G. Giraud**: Certain non-linear problems of Neumann and certain non-linear mixed problems.—**M. Centnerszwer** and **J. Szper**: The electrolysis of fused sodium metaphosphate.—**K. Dziewoński, Mlle. J. Krasowska**, and **Mlle. J. Schoenówna**: Researches on the acenaphthene sulphonic acids.—**R. Malachowski**: The equilibrium in aqueous solutions of aconitic acid.—**Cz. Kuźniar**: The origin of the mirabilite in the deposits of potassium salts at Holyń and at Siwka.—**L. Marchlewski** and **A. Boryniec**: The absorption of ultra-violet rays by certain organic substances.—**J. Wlodek, C. Strzemieński**, and **E. Ralski**: Researches on 'Czerwone Wierchy', Tatra and Bielsko soils in which mixed plant associations are developed.

GENEVA.

Society of Physics and Natural History, Mar. 19.—**P. Rossier**: The nature of Purkinje's phenomenon. In an earlier study, the author has shown that the intensity of the source and the acuteness of the maximum of the eye sensibility curve vary in the same sense. A more complete calculation enables the conclusion to be drawn that this variation of sensibility is insufficient to explain the observed phenomena: the known diminution of the wavelength of maximum sensibility with the intensity ought to be preserved.—**Ed. Paréjas**: Results of the Harvard University geological expedition in the Canadian Rockies (Jasper National Park), 1929. Note No. 3. The Trias of the Athabaska Valley. The Upper Trias (Norian to Pseudomonotis, cf. subcircularis) has been recognised in the valley of Vine Creek, a tributary of the Athabaska, to the north of Jasper. The underlying formations of Cold Sulphur Spring, Corral Creek, and Fiddle River, attributed to the Trias, are also marine. They have a pronounced detrital character marked by the abundance of the mica grit, the presence of conglomerates and of magnesian breccia of alpine type. The Trias of Jasper Park, about 200 metres in thickness, rests on the Rocky Mountain quartzite formation (Upper Palæozoic).—**E. Joukowsky**: The phreatic sheet of Soral (Canton of Geneva). A well showed the following in section, from top to bottom: post-glacial deposits, 5 m.; Würmian end moraine, 20 m.; fluvio-glacial gravel, 10 m.; stratified clays and sand, 14 m.; fluvio-glacial gravel, 17 m. The water table was at a depth of 58·5 m. The thickness of the water-bearing layer is at present 9·3 metres. The variations of level recorded with the limnigraph during a month, show a direct relation with the pressure recorded on the barograph. Between February 1930 and March 1931 the level has risen more than two metres.

April H. 23.—**Saini** and **J. Weiglé**: A possible transformation of maleic acid into fumaric acid. The authors tried to see if a magnetic field could convert maleic acid into fumaric acid. The results of experiments in a magnetic field of intensity between 5000 gauss and 8000 gauss show that this transformation does not occur.—**E. Briner, A. Demolis, H. Paillard**: The ozonation of aldehydes and the theory of active molecules. Studying this ozonation, the authors have proved an intense activating action exercised by the ozone on the molecules of oxygen. This action markedly increases the yield of oxidations carried out with ozone.—R. Wavre: From the human scale to the terrestrial scale. The author discusses a remark of Helmholtz which the Wegener hypothesis makes of current interest. He shows that the duration of certain phenomena of hydrodynamical order increases as the square of the dimensions. For example, the large but very slow currents in the midst of the terrestrial magma have quite well been able to last for millions of years, even although this magma were very viscous. Care is necessary in passing from the laboratory scale to the terrestrial scale.—G. Tiercy: Silvering telescope mirrors. The method of E. Schaer employed at the Geneva Observatory. The author describes the composition of the baths and gives the characteristics of the Schaer method adopted for silvering the Observatory mirrors.

No. 3224, VOL. 128]

Scientific Men as Administrators.

FREQUENT reference has been made in these columns to the relative positions of administrative officers and of scientific and technical officers in the service of the State. As we remarked when discussing the report of the Royal Commission on the Civil Service (NATURE, Aug. 8), proficiency in science whether pure or applied is regarded almost as a disqualification for a high administrative post, the suggestion being that knowledge of a particular branch of science makes a man biased in favour of that branch. The corollary of this proposition is that the best administrator is one who has no scientific knowledge at all, even though every day he has before him problems which can only be understood and solved with the aid of science.

It is not strange that this paradoxical condition of things should have resulted in much dissatisfaction among scientific and technical officers in Government service, both in Great Britain and overseas. They find themselves frequently in distinctly inferior positions in comparison with those occupied by men who graduated in literary or historical subjects, and their rates of pay as well as promise of promotion are similarly on a lower scale, purely because they chose to take science for their degrees. No one could suggest for a moment that a science student is essentially of lower mental capacity than one whose inclinations are in literary fields, and it cannot be held that the knowledge and training he receives in his scientific course are detrimental to efficient service in a modern State. Notwithstanding this, we find that of two men with equal academic distinctions in the two different fields, one with a science degree is expected always to be subordinate to his fellow who graduated in ancient languages and literature.

Specialists are largely employed as a matter of insurance to safeguard the production of animal and plant materials and of minerals, or to watch over the health of the community. The last function is carried out by the medical officers, who are members of a well-organised and by no means inarticulate profession. It is far otherwise with most specialist services, and here the differential rate of pay, which particularly in a Colony may mean a lower position and social life, is a serious matter.

The problems to be considered by the scientific man in the Colonial Services are not those of his own choice; they are governed by local circumstances. Text-books and laws to which he can refer are non-existent, for the difficulties of each country have an individuality of their own. Such a man is paid on an average about twenty-five per cent less than his brother of equal academic standing, from the same university, who is in the administration—and this is often associated with longer terms of service, fewer higher posts to which he can aspire, and always by a relatively lesser pension. As compared with an academic career, the initial pay and security are often better, but there are singularly few posts carrying salaries equal to those of professors in the greater universities. The relative liberty of the latter is so well known to their students that those with the highest academic distinctions prefer teaching and research to State service.

Of course, especially in modern civilisation, the State must employ men of the highest class in all its services. This is particularly the case in the Civil Service, which was the concern of a Royal Commission in 1912–14. A Treasury Committee (1917) afterwards remodelled its examination through which the Higher Civil Service, the Indian Civil Service, and certain Foreign Office, Consular, and Colonial Services are recruited. In this examination all candidates must first qualify in a section which allows 100 marks each for five compulsory subjects, namely, essay, English, present day (questions on contemporary subjects), everyday science, and auxiliary language, and 300 marks for vivâ voce. In another section 1000 marks are distributed, *at the choice of the candidate*, amongst sixty-one subjects that represent every side of the teaching of universities. The age limit is twenty-four, and the examination is obviously arranged in reference to university courses of instruction. The following sciences are represented by papers of Lower and Higher Grades, for each of which 200 marks is offered, and both grades of which can be taken: chemistry, physics, botany, geology, physiology, and zoology. Of kindred subjects a candidate can take five papers, each of 200 marks, in mathematics, and usually there is little blending of this subject with science. The same remark applies to engineering and geography, to which are severally assigned 400 marks; to two sections of anthropology, each 100 marks; and to agriculture, 200 marks.

Science candidates have little to criticise, for the compulsory subjects represent a necessary, minimal, general education. Still less can they object to the vivâ voce, for it is the only practical means of estimating personality, especially as seen in the gifts of sympathy, readiness, and resource. In any event, it reduces an element of uncertainty common to all examinations, and the pure examinee will be accepted even if he possesses none of these gifts, and it is to be hoped that his deficiencies will be hidden in a useful, impersonal job. The study of the marks assigned in the vivâ voce is interesting, for it shows that the qualities sought are not peculiar to candidates from any single class of life or of learning, the examination being above suspicion.

The small importance of the subject of "Everyday Science" is perhaps more open to criticism in a State which largely owes its position to the application of science. The average individual would understand, by such a title, an elementary knowledge of his own actions and of the world around him. The examiner (1930) is apparently dominated by academic teachings, since candidates are asked about relativity, molecules, and atoms, the distance of heavenly bodies, adaptations of birds for flight other than wings, communal life among insects, and so on. To judge by the marks, this was a satisfactory paper, but such questions could be answered better by judicious cramming than by a general scientific education. In the separate sciences the Higher Grade is of similar standard and type to that of the final honours examination of universities, and so should afford a reasonable scope to specialists in science.

The schemes of the voluntary papers are all on the same lines; they include all the subjects taught in universities, and thus reflect the life and requirements of the nation. To ensure a Civil Service ready for all emergencies, each side of educated thought and progress should be adequately represented therein. It is accordingly evident that if any branch of learning, which is vigorous and promising in the country, should show numerical poverty in the Civil Services, there is a condition which calls for explanation and possibly remedial measures. Applying this criterion to the present state of the Civil Service, we find there a startling lack of scientifically educated men. In these circumstances it is difficult to understand how the independent scientific services of the State can be understood and properly used by an administration unfamiliar with the methods and aims of scientific workers. Here are the analysed figures for the higher examination of the Civil Service for 1930:—For the Foreign Office and Department of Overseas Trade, only 1 candidate out of 67 took any of the voluntary scientific subjects. For the Home Civil and Indian Civil Services and for the Eastern Cadetships there were 316 candidates, of whom only 20 presented science as the predominant group of their choice. Of these, 17 offered lower and 9 higher chemistry; the number in physics was 15 and 10; botany, 4 and 3; geology, 5 and 1; and zoology, 4 and 3. There were no candidates in physiology; 4 candidates sat for engineering, and 2 for geography.

Civilisation being so closely coupled to-day with the developments of science, these figures reveal a position which should be altered. These cover every field in Great Britain and the Dominions, but at present are mainly biological in the Crown Colonies. The basal factor in the latter is the native of the country, who is being profoundly altered by the introduction of hygienic conditions. The problem of the 'poor whites' in the Southern States of America has its counterpart in almost every Oriental country. Malaria, yellow fever, bilharzia, and a host of other diseases are ceasing to be endemic in successive generations. As a result, the future natives of many of these countries are likely to be physically and mentally superior to their ancestors. To-day there is everywhere an increasing call for science in the development of the races themselves and of the countries which they occupy. It follows that success in administration here will increasingly depend not on the knowledge of the history of colonisation and of the theories of governance, but on the scientific understanding of the changes wrought in the last hundred years and of the psychology of the governed.

Teachers of science must wake up to their responsibility in this matter, which is to direct the attention of suitable candidates to the needs of the State. For research, students of peculiar aptitude and mentality are required, and they for the most part desire to concentrate on one section of natural phenomena. There is a bigger class who have no such predilections in the early stages of their work. They want to understand all the diverse sides of science—physical, chemical, biological—with often a special fancy towards the economic, rather than to follow out any one line. They are as fitted as any other students for appointments in administration, and it is to this class that the Empire must look for its future administrators. Such men would have peculiar sympathy with the work of scientific men in their districts and encourage the application of their economic results. Their knowledge would inevitably create in themselves a deep interest in the country in which they dwell, thus adding to their happiness and efficiency. A special responsibility therefore rests upon those at the universities who have it in their power to influence likely science students to compete for administrative posts in the Civil Service.

Jules Janssen, 1824–1907.

Œuvres scientifiques. Par Jules Janssen. Recueillies et publiées par Henri Dehérain. Tome 1. Pp. vii + 545 + 12 planches. Tome 2. Pp. 648. (Paris: Société d'Éditions géographiques, maritimes et coloniales, 1929.) n.p.

THESE two imposing volumes are the second fruits of the devotion of Mlle. Janssen to the memory of her father. On Janssen's death, in December 1907, she took upon herself the task of raising a memorial of his long and distinguished scientific career, and with the co-operation of M. Dehérain, whose father and Janssen had been close friends from boyhood, a fund was accumulated for the erection of a monument on the terrace of the observatory at Meudon, which, during a period of more than thirty years, "he had paced with slow and regular step". The undertaking was on the point of consummation when the War supervened, and, laying aside all other considerations, Mlle. Janssen devoted herself throughout the ensuing period of hostilities to the care of the wounded. At the conclusion of the War this project was resumed, and on a beautiful afternoon in October 1920, a distinguished company paid homage to the memory of the dead astronomer.

Monuments are symbols; but a great man's works are realities; they alone are his true memorial. During his long life, Janssen wrote much but he never published a book. Mlle. Janssen accordingly began the collection of the articles and the writings which her father had contributed to various periodicals, and in this again she had the assistance of M. Dehérain. Unhappily, she has not lived to see the completion of this second mark of filial devotion. Among her last wishes was the desire that M. Dehérain would carry the project to fulfilment, and the volumes before us testify that he has discharged his commission in a manner of which she would assuredly have approved.

Janssen's long list of scientific works began in 1859, with a carefully prepared and illustrated paper describing experiments on a property of the eye relative to radiant heat—a thesis which was presented for the doctorate of physical science to the Faculty of Sciences of Paris. This involved him in some correspondence, and later in work with the ophthalmoscope. It was a natural transition from this to the spectroscope and spectrum analysis, which, in its turn, directed his attention to the heavenly bodies, and thenceforth Janssen's labours were almost exclusively astronomical in character. His first astronomical problem was concerned with the possibility of detecting the existence of a lunar atmosphere by means of the spectroscope. Many years later he returned to this subject and was able to settle the question definitely by observations of a partial eclipse of the sun.

Janssen's name will long be remembered through two brilliant pieces of work—his invention of the method of observing solar prominences in full daylight, and his beautiful and still unrivalled photographs of the solar surface, showing the granulations which he named the "réseau photosphérique". The former achievement, which, as is well known, was announced to the Paris Academy of Sciences simultaneously with that of an identical but independent discovery by the late Sir Norman Lockyer, might almost be said to be the most important event in the history of solar physics, for with it began the long and extremely fruitful course of observation—aided later by the spectroheliograph—which has culminated in the present physical theory of solar and stellar atmospheres. The French Government was not slow to recognise the significance of the discovery, and it at once set about the establishment of an observatory for Janssen, which, in spite of the disastrous war of 1870–71, was erected, first at Montmartre and later, in 1876, at Meudon.

Mention of the Franco-Prussian War reminds us of Janssen's historic escape from besieged Paris by balloon to observe the solar eclipse of December 1870. "En dépit du siège," he wrote to the Academy in October of that year, "et sans avoir à demander à nos ennemis le passage à travers leurs lignes, un observateur pourrait, au moment opportun, se diriger vers l'Algérie par la voie aérienne ; il emporterait seulement avec lui les parties les plus indispensables de ses instruments, sauf à les compléter à Marseille avant l'embarquement. Si l'Académie veut bien m'accorder son appui pour la continuation des travaux dont je viens de l'entretenir, une partie des ressources pourrait être employée à la réalisation de ce projet et je m'offrirais pour tenter ce voyage, heureux de donner ainsi à la science ce témoignage de mon entier dévouement." The observations, unfortunately, were ruined by clouds ; but the incident is eloquent of the ardent spirit of the man.

These are the achievements by which Janssen is mostly remembered ; but it should not be overlooked that much of his other work has become so absorbed into the traditions and common data of astronomy, that its authorship is almost forgotten. It was Janssen who gave us the term 'telluric lines', and he not only did work of fundamental importance in identifying such lines, but also placed their origin beyond doubt by observing them in the spectrum of a bonfire at a distance of 13 miles. For his observations of the transit of Venus in Japan in 1874 he invented a "revolver photographique", which is, in principle, the modern cinematograph, yet who thinks of Janssen in connexion with that device now ?

The volumes under consideration, which are enriched by some beautiful photographs, tell of a long lifetime devoted with conspicuous success to the service of science. M. Dehérain has done his work well ; he has given us a fitting memorial of a great man.

Physical Attributes in Plant Processes.

Life Movements in Plants. Edited by Sir Jagadis Chunder Bose. (Transactions of the Bose Research Institute, Calcutta, Vol. 6; 1930–1931.) Pp. vi + 211. (London, New York and Toronto : Longmans, Green and Co., Ltd., 1931.) 18*s*. net.

IT is now almost axiomatic that, to get what you want involves continuous perseverance, often patient repetition, and sometimes decades of undivided attention and devotion. Perseverance underlies the success of things which primarily may have seemed impossible. Men and women have fought, have devoted their lives, and have even given their lives, in order to achieve the apparently impossible. Some aims are impossible, and that is one reason why, whereas some champions have been successful in reaching their ultimate goals, others have fallen by the wayside.

We wonder into which category Sir Jagadis Chunder Bose will ultimately be placed. For about thirty years now, he has fought the cause of the physiological against the purely physical in plant physiology ; also to prove that plants and animals exist by virtue of the same inherent phenomena. "The results of the experimental investigations that have been carried out in my Laboratory during the last thirty years suffice to prove that the mechanism as well as the life-processes in the plant and in the animal are essentially similar." His prolific publications go to show his firm conviction of this.

The physiological concepts of Bose, his firm belief that physiological phenomena succeed in explaining where physics fail to explain certain life processes, are well known to every experimental physiologist. To lift the science of plant physiology from the morass of chemistry, physics, and mathematics and to relegate it to a more exclusive position has been the life-work of this experimentalist—this maker of a mixture of poetry and science, as Prof. Donnan chose to call him. Bose is not only convinced of such possibilities, but also believes them to be proved. But we are still looking forward to the time when more of the ‘ physical physiologists ’ enter the lists with our physiological knight-errant and bring the issue either to a more definite understanding or, better still, a decisive climax, one way or the other. This state of scientific chaos, which exists in the mind of the physiologically interested onlooker, seems to be due apparently to two reasons: one, Bose's ignoring the work of his contemporaries to a large extent, and the other, the silence of his contemporaries; the latter probably being the more cogent.

This new publication helps the reader little in this respect. It is edited by Bose, who himself contributes short essays, interspersed as introductions to the other papers ; but every author of the various chapters is a worker at the Bose Institute and, judging from the work done and the conclusions arrived at, each one seems to have imbibed to the full the philosophy of his director.

Many interesting new experiments are recorded, with methods constructed on true ‘ Bosian ’ lines, which need no introduction to the physiologist; but nothing very new is added to our stock of knowledge, hypotheses or contentions, where plant irritability and the ascent of sap are concerned.

We would rather see references to such works as Pfeffer's “ Plant Physiology ” and “ Strasburger's Text-book of Botany ” omitted in favour of more up-to-date works, and the conclusions of contemporary plant physiologists either made compatible with those of the vitalist or completely and irreparably refuted. But probably the others are really to blame. An almost eerie silence has pervaded this branch of botany for some years, which leaves us almost bewildered with perplexity. What is the reader to believe ?

The revival of a drooping leaf on irrigation, and correlated experiments, demand much attention of Bose and his co-workers in “ Life Movements ”. The rapid erection of a wilted, vaselined leaf on irrigation, as shown by Bose on pp. 14 and 15, and the failure of a poisoned leaf, similarly treated, to respond to the supply of water, certainly seems, as the author claims, to demonstrate the presence of some type of propulsive activity within the plant, which is independent of transpiration. The attainment of the erect position in about three minutes is indeed very quick, unless *Centaurea lanata* is a physiological monstrosity. The experiment is simple enough, ‘ fool-proof ’ as Bose described some of his experiments at the meeting of the British Association at Oxford in 1926. Why other physiologists cannot check such a conclusion by simple repetition of the experiment, especially one which is so antagonistic to the generally accepted conceptions (so far as we dare have any) of the ascent of sap, is very difficult to understand.

Chapter iii. is devoted to further work along the same lines on the characteristics of the erectile response of leaves, by U. C. Sen. Varying conditions are examined and their results recorded. Bose himself, in Chap. iv., describes his ‘ diagnostic ’ methods for recording erectile response of the leaf by the electromagnetic tapper and the automatic recorder. Not so ‘fool-proof’, we imagine ; for, here, Bose is in that electrophysiological element peculiar to his own ingenuity. Further conditioning factors are examined by G. P. Das in Chap. v.

The effect of temperature of the water of irrigation on the rate of the ascent of sap is recorded by J. P. Sirdar in Chap. vi. Very important data are brought to light. Suction is annulled below 5° C. and then follows a steady logarithmic curve to 35° C. At the maximum temperature, investigations ceased. This is surprising in a worker who has clearly boosted the physiological against the physical. At just above 35°, many plant physiological processes begin to fall off, owing to the so-called killing of the tissues. In these inquiries, with vital propulsions and rhythmic activity at issue, we should expect that studies of the effect of temperature just above 35° would have been equally as important as those below. The results obtained from such temperatures and incorporated in the graph on p. 69 might have proved of the greatest utility. It is a pity that this has not been done, especially since previous experiments with water only at temperatures of 4° and 30° and 4° and 35° gave results which might have been expected, whatever view of the mechanism of the ascent of sap we are prepared to accept.

The effect of various normal and artificial factors on the pulsatory movement of the leaflet of the now too familiar *Desmodium* constitutes the basis of the work by Bose and Deb, recorded in Chap. viii. Here, again, greater value might have been attached to the results, when examining the effect of temperature, had the investigators used several

G 1

temperatures *seriatim* instead of the minimum of 4° and the optimum (?) of 35° only.

Coming to the identity of plant with animal mechanisms, B. K. Dutt, in Chap. xii., shows that just as excitatory impulse is initiated by a specific polar action of an electrical current in the conducting nerve of an animal, so it is in the case of plants. Observations were made at different values of E.M.F. Another all too familiar plant, *Mimosa,* was used as the subject. After all, such plants are almost physiological freaks, and to generalise from such particular cases is scarcely good logic, or fair play. Bose and N. N. Das carried out similar experiments on the nerve tissue of *Bufa melanosticus* and, having obtained like results, conclude that " The results conclusively prove that the transmission of impulse in plants is an excitatory process of the same nature as that of the nervous impulse in animals ". Similar conclusions are arrived at as a result of experimentation with the nerve of *Rana* and also *Mimosa.* But all this conveys nothing new so far as theoretical conceptions are concerned.

The book concludes with some work by Prof. N. C. Nag and H. N. Banerjee on the " Proteolytic Enzymes in *Carica papaya* " and by Nag and K. N. Bose on " Chemical Examination of some Indian Medicinal Plants ". Nag and Banerjee disagree with Willstätter, who considers that papain contains only a single protease, and this of a tryptic nature. Their findings come more in line with those of Vines, who states that there are two enzymes present, one of a peptic nature and the other ereptic. In this chemical work it is refreshing to see contemporary and past investigations taken into account, which considerably enhances the value of the results obtained.

This chronicle of contemporary work being done at the Bose Institute, Calcutta, gives us very little that is now startling. Yet it serves one valuable purpose. It supplies much evidence which may easily be verified by other workers. We should like to see this done ; but are beginning to despair of such hope. In any case, the book should be on the shelf of every physiologist, for if he is sympathetic with the views of Bose, it will help to give him still further satisfaction. If, on the other hand, he supports the more physical views and prefers to segregate plant from animal processes, the book should give him another opportunity for putting his own house in order. But we doubt if the book will carry enough conviction to change the opinions of anyone.

L. J. F. B.

Living Zoology.

Principles of Animal Biology. By Prof. Lancelot T. Hogben. Pp. xxiv + 332. (London : Christophers, 1930.) 8*s.* 6*d.* net.

THE main problem before the writer of an elementary text-book is usually what to leave out. Prof. Hogben, by leaving out most of the contents of other elementary text-books, has succeeded in writing a book which should interest not only the intelligent student, but also his teacher. Throughout it the animal is dealt with as a group of events rather than a structure. The anatomy of the circulatory system is only considered after a general account of its physiology has been given ; the brain and its nerves are rather summarily described after a more detailed account of reflexes and the behaviour of isolated nerves and muscles.

What is more, zoology itself appears as a growing and far from adult science. The second part of the book is devoted to genetics and evolution, and comparative anatomy is introduced not as an end in itself, but as a means to classification. Thus the molluscs are described to explain why Cuvier's classification was superior to Lamarck's, and the cœlenterates in turn justify Leuckhart's emendation of Cuvier. So much space is devoted to the evolution of zoology, that the even more fascinating though more speculative study of the evolution of animals is perhaps treated a little summarily. Thus the clearest demonstration of evolution is to be found in the study of continuous change in such organisms as *Micraster* or *Gryphœa,* and some account of these gentes might have been more appropriate than a repetition of Dr. Buckland's alleged joke about glacial striation.

A very satisfactory account of elementary genetics is given, though this does not include the fact, which might have induced the author to alter the argument of his last two pages, that organisms can now be produced experimentally which will breed freely together, but not with their parents. A set of problems in genetics, though well chosen, unfortunately refer entirely to the domestic fowl and *Drosophila melanogaster.* Just as good data could have been obtained from the genetics of men, other mammals, fish, crustaceans, and gastropods. It would seem that the very men who are trying to dethrone the old morphological types such as the frog and dogfish are in danger of setting up *Drosophila,* an animal whose genetics are far from typical, as the principal genetical type.

It is doubtful how far this book will be adopted as an elementary text-book of zoology. Undoubtedly a medical student who had mastered it would be far better prepared for his medical studies than is now usually the case. But from what one knows of the history of university teaching, so violent a change is improbable. If it is made at all, it is likely to be made in stages. Meanwhile we can think of no volume of its size more suitable than Prof. Hogben's to supplement the orthodox zoological text-book, in the hands of both intelligent students and teachers. In this capacity, at any rate, it is to be hoped that it may find a wide circulation.

Short Reviews.

The Origin of Life. By Gilbert Rumbold. Second Impression. Pp. 128. (London: The Norfolk Press, 1931.) 5*s.*

THE true philosophical mind is not connoted exclusively by an ability of learned and scholarly criticism of existing theories, but primarily by the inquisitive attitude which has really given birth to philosophy, and the courage and power of stating one's findings about the problems considered. The author of "The Origin of Life", though not a professional philosopher, displays in his book a true philosophical mind in presenting to us his particular answer to the time-honoured question which he asked himself, "What is it all about?"

Seeking unity of structure and purpose in the world in which we live, the author claims to have found a more adequate explanation of life by means of his "Proton Theory of Living Matter". This theory, which reminds one of a combination of Epicurean physics with Leibnizian monads and Darwinian selectionism, the whole mashed with the language of contemporary physics, is simple and suggestive. In order to bridge the gap between mind and matter, the author imagines the existence of 'egos' or 'earth-minds' of which human minds are but a sub-class. These 'egos' have the property of expressing themselves in the world of matter, the size of their 'modes' of expression being no wider than the proton nucleus of an atom. Then intervenes the principle of natural selection, which directs the 'egos' to meet other 'egos' and thus form the original cells of the living matter. The establishment of a proper hierarchy between these formations leads to an all-embracing explanation of life, while secondary developments of this theory offer tentative explanations of habit, instinct, sex, and suggest possible solutions of some higher problems of philosophy.

These views are indeed very interesting; but before discussing them in detail, one would wish Mr. Rumbold to expand his epitome in such a way as to show exactly the intermediary steps between his dogmatic assertions, and to indicate the connexion of some of his expressions with the standard theories they inevitably conjure up in his readers' minds.

T. G.

Annales de l'Institut Henri Poincaré. Fascicule 2, Vol. 1. Pp. 77-203. (Paris: Les Presses universitaires de France, 1931.) 35 francs.

THE first number of the *Annales* was noticed in NATURE of Oct. 11, 1930 (p. 564). In the second number we have de Donder on Einstein's theory of gravitation, Pólya on some points in the theory of probability, Lévy on the fundamental theorem of the theory of errors, and Kostitzin on some applications of integral equations.

De Donder's paper is a summary of a series of six lectures dealing not only with relativity, but also with wave mechanics and thermodynamics. He tries to show that, contrary to a widely held belief, there is no need to modify the general theory of relativity, for if this is understood in a sufficiently wide sense it is in harmony with the most modern theories of wave mechanics. There are several references to the work of J. M. Whittaker, and it is pointed out that the material tensor, the electric current, and the photonic currents properly so-called are all expressible in terms of Whittaker's photonic potentials.

Pólya's paper is divided into two distinct parts. The first deals with a characteristic property of the Gaussian or normal law, while the second deals with other laws of frequency, obtained by the superposition of small causes which are not independent of one another. Lévy's paper also deals with the normal law.

Kostitzin's paper deals with integral equations which have an infinite number of solutions. He advances the view that by restricting ourselves to linear equations with unique solutions we get an impression of definiteness and causality in Nature which is valid only as an approximation. The multiplicity of solutions corresponds to the more modern view of indeterminacy in detail, with definiteness arising only from a statistical average. In an interesting preface it is suggested that the sceptical and even pessimistic tone of Poincaré's last utterances on the physics of his time was due to his insight into its concealed weakness and his power of anticipating future developments.

H. T. H. P.

Animal Ecology and Evolution. By Charles Elton. Pp. 96. (Oxford: At the Clarendon Press; London: Oxford University Press, 1930.) 4*s.* 6*d.* net.

THIS little book consists of three lectures, "The Regulation of Numbers", "The Significance of Migration", and "The Real Life of Animals". An environment is an entity composed of plants and animals, the species of which are constant. But it is pointed out that the numbers of the different species of animals vary not only in accordance with the periodic changes of temperature, rainfall, etc., but also in an irregular manner. There may be an optimum density for a species and, when its population varies too far from this, the species changes its behaviour. The most obvious change is that of migration into a region which may be very different from its old home, a new habitat. It seems to be an inherent impulse, for the individuals which migrate are often annihilated, without in any way eliminating the impulse in the species when the disadvantageous circumstances which caused it recur.

The emphasis on migration rather hides the fact that every free living animal has in the small affairs of its life a considerable amount of freewill. Examples are given, all from air living animals, but we think they would be easier to understand and found to be even stronger in aquatic forms. The third part is really an examination of these views with regard to the current conceptions of evolution. The idea of all structure in animals having an adaptive relation to the environment is surely out of date amongst zoologists, as also is the formation of species by natural selection by the accumulation of small variations. The whole question of mutations arises, and we agree that "without the aid of any adaptive advantage" such will never be able to spread beyond a certain point. But, if mutation has once occurred, the potentiality is there in the species and it may often reappear. We do not propose to follow the author in his discussion. We content ourselves with thanking him for indicating many sides of the study of living animals that may be pursued with advantage. J. S. G.

The Heavens and the Universe. By Prof. Oswald Thomas. Translated by Bernard Miall. Pp. 288. (London: George Allen and Unwin, Ltd., 1930.) 7*s.* 6d. net.

THIS book has been written by a star-lover for star-lovers. It is couched in simple, conversational language, suitable for the earnest but not very learned mind. The author has for many years been accustomed to conducting night excursions into the woods near Vienna for the purpose of observing and studying the heavens, and he here tries to extend the usefulness of his talks to a wider circle. He has done very well. The book will appeal to the many persons whose interest in the sky will always be primarily a sentimental one, but who, nevertheless, feel a desire to know something of what the astronomer by his cold, intellectual inquiry has been able to discover. Prof. Thomas tells him this in a way which he will appreciate; the style is humane without undue preciosity. Anecdotes are common and usually to the point, and the illustrations have been successfully conceived.

The professional astronomer will probably meet with statements which will seem to call for criticism, but if he is wise enough to remember the purpose of the book he will turn a deaf ear to them. They are, in any case, few and of little significance, and the negative virtue of freedom from inaccuracy counts for little beside the many positive virtues which characterise the book. The translation—which achieves the merit of not being recognisable as such—is very satisfactory. Prof. Thomas's book is possibly the only popular astronomy which contains no photographic illustration. This, it must be confessed, is a defect, but the reader will probably have become so familiar with some of the admirable celestial photographs now available in such a variety of ways that the disadvantage will be reduced to a minimum.

Intermediate Mechanics. By D. Humphrey. Vol. 2: *Statics and Hydrostatics.* (Longmans' Modern Series.) Pp. xi + 438. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 10*s.* 6*d.*

THIS very competently written volume, designed to cover "all requirements up to Higher Certificate and University Scholarships standard", leaves one with a dream-like feeling that the Saturnian days of the old Cambridge mathematics have not yet passed away. Here are no philosophic doubts concerning the definitions of force and matter; a balance must still be (i) *true*, (ii) *sensitive*, (iii) *stable*, and (iv) *rigid*; the conventional systems of pulleys are carefully and clearly explained, with illustrative examples of every degree of ingenuity, and not so much as a picture of a Spanish Barton: and all our old problems concerning rods in bowls, jointed rhombuses, slipping ladders, sliding rings, jamming drawers, and examples of practically every type of question that the perverted imagination of an examiner can suggest, are assembled under their due headings and worked out in clear and orderly fashion. The book expands beyond the limits usually assigned to such work in well-written and fully illustrated chapters on beams and catenary problems, on graphical statics, and on virtual work.

There is no doubt that the book will provide all the guidance necessary for candidates taking examinations of the Intermediate standard, and will serve as a useful introduction to more advanced work. Whether books of this type are of real assistance in the training of engineers or of mathematicians is a matter concerning which we do not express any opinion. A. F.

A Compilation of Culture Media for the Cultivation of Micro-organisms. By Prof. Max Levine and H. W. Schoenlein. (Monographs on Systematic Bacteriology.) Prepared at the request of the Society of American Bacteriologists and financed by a Grant from the Digestive Ferments Company, Detroit, Michigan. Pp. xvi + 969. (London: Baillière, Tindall and Cox, 1930.) 67*s.* 6*d.* net.

THIS large volume is a compilation of various media used for the cultivation of bacteria, yeasts, and moulds. In all, about seven thousand have been assembled. These have been subdivided primarily into groups on the basis of physical characteristics and the nature of the solidifying agent used, and secondarily upon the chemical characteristics of the media. The use of each medium is indicated.

The book is one of a series of monographs on systematic bacteriology and was prepared at the request of the Society of American Bacteriologists. References are given with each medium, and an excellent list of references at the end of the volume. The compilation of so vast an amount of scattered material is difficult, and has been admirably done. The book is a valuable addition to bacteriological literature.

The Ecological Viewpoint.*

By Prof. J. W. BEWS, Principal of the Natal University College.

THE study of the history of science, and particularly the detailed history of single sciences, is of very great importance for all scientific workers. The history of botany is as interesting as any. As the content of the subject, like other sciences, increased so vastly during its development, specialisation in modern times became inevitable. Specialisation in itself is not necessarily a bad thing, indeed it is necessary for the progress of science; but by itself it is not enough. Specialisation should be combined with as sound a knowledge as possible of the subject in general.

The question is whether botanical specialisation in these days has become universal. Are there any botanists left who adopt the right attitude of mind? The answer is that this is exactly the claim put forward by the ecologist. Ecology, as its followers have maintained, is not a special branch of botany; it is simply a way of looking at the subject. The ecologist adopts what one might describe as the holistic point of view. Ecology seeks to explain, as fully as possible, not only why plants occur where they are found, but how and why they are as they are, and why they behave as they do. It is, therefore, essentially synthetic. It draws upon palæobotany, for example, because to understand why plants are as they are to-day it is necessary to study their past history. The study of plant pathology is essentially ecological because disease in plants, as in animals, is due to maladjustment to their environment. Experimental work in ecology, as Clements has pointed out, is purely a study of evolution, and the facts of the latter are the materials with which taxonomy deals. The value of genetics to the ecologist is sufficiently obvious. Ecology and physiology are clearly so allied that the latter may very well be included in the former.

SOUTH AFRICAN ECOLOGY.

In many ways in South Africa I was fortunate, for, when I began work here in 1910, I was brought closely into touch with the late Dr. Medley Wood, with Dr. T. R. Sim, with Dr. Marloth, Mr. J. S. Henkel, and others from whom I was able to learn a great deal in a comparatively short time. Descriptive ecology can, of course, be made as detailed as one pleases, but the recognition, description, and rough general analysis and distribution of the major plant communities in Natal and some other parts of South Africa could be carried through fairly rapidly.

The second stage of my South African ecological studies dealt with the developmental history of various plant communities, or what is commonly referred to as plant succession. One of the most important things is to be always on the lookout for cases of plant suppression, that is, examples of one type of plant being killed by another. For example, as one walks along the margin of a forest one can often discover the dead remains of light-demanding shrubs just within the outside belt of trees. This means that the forest is progressive and is gaining ground at the expense of the surrounding grassland. Similarly, in the grassland itself, tufts of deep-rooted wire grasses (*Aristida*) may be found being smothered by the more shallow-rooted, more luxuriant red grass (*Themeda*).

Everywhere, a dead or dying plant should act as a 'flag signal' to the ecologist. The immediate cause of death is usually the attack of some fungal or bacterial parasite. But the more remote causes are various, depending usually, in a general way, on the lack of power to respond to changes in the environment, and, since the biotic environment is most liable to change, death is most often brought about in this way. One stage of development of the plant community gives way to the next, until a climax, a more or less stable condition, is reached.

As soon as one has obtained a sufficient number of carefully recorded comparative observations in different areas, a complete analysis of the full developmental history of any plant community can be given, and, for the more important plant communities in South Africa, that has been done. Over the whole eastern side of South Africa the main course of the plant succession is similar to that found in other parts of the world. Bare surfaces are colonised by light-demanding plants, among which annual weeds and other 'ruderal' plants are common and characteristic. The earlier stages of all succession on dry land are more xerophytic than succeeding stages.

In a pastoral country such as South Africa, the proper management and control of the natural pastures is of paramount importance. It is possible to sum up almost in a single sentence what are the results of overstocking, veld burning at unsuitable seasons, and other modes of interfering with the natural vegetation. Man's interference always tends to send back the plant succession. Climax stages are destroyed and earlier stages take their place. Over wide areas of climax grassland this is undesirable, for the earlier wire-grass stages are less palatable and less nutritious. On the other hand, in forest climatic areas it may be a good thing to replace trees and shrubs by earlier pure grassland stages. A careful study of the plant succession can show us when burning the grass is necessary and when it is not. There are many other practical problems in connexion with veld management that can be solved by studying plant succession, plant indicators, and, in general, applying field ecological methods.

Pioneer species tend to be very widespread; they are more plastic physiologically; they show a greater range of physiological variation. It is also particularly interesting to note that pioneer species are usually to be regarded as advanced types from the phylogenetic point of view. On the other hand, the species that belong to later stages of the succession differ in all these respects from the pioneers. They are much more numerous than the pioneers, and they belong to a greater variety of growth forms, since, in addition to the dominating species, there are so many that occupy subordinate positions. One of our South African forests, for example, does not consist merely of trees. There are abundant climbing plants, epiphytes, shrubs, undershrubs, and herbs, as well. Since they vary so much in form, so also they vary in their phylogenetic standing. Many of the trees are relatively primitive in this respect. Some of the subordinate forms may be very advanced. For the climax stages the living environment (or biota) is as important as, if not more so than, the inorganic environment.

---

* From the presidential address delivered on July 6 to the South African Association for the Advancement of Science, at Grahamstown.

The third phase of the ecological work which I have been privileged to carry out in South Africa followed naturally from the previous work. It consisted in the study of the interrelationships of taxonomy (based on phylogeny) and field ecology, and in particular dealt with the origin and migrations of the South African flora and the evolutionary history of plant forms. More recently I have applied the same methods to the study of a single group of flowering plants—the grasses.

By combining the study of taxonomy with the study of distribution it soon became apparent that the oldest flora lay to the north of us, in the great moist tropical areas of Africa. In support of this view is the further important fact that the tropical flora of Africa in many of its elements unites closely with the tropical floras of Asia and America. It is probably the oldest angiospermous flora in the world. In South Africa, from this tropical element, a subtropical one has been produced, which has become more and more highly evolved and modified in response to the winter resting season and dry conditions generally, until in our Karroo regions and dry desert areas of the western side we find the culmination of the process. The Karroo has a flora which has good claims to be ranked as the most highly evolved in the world.

The temperate element of our flora, however, is rather distinct from the tropical and subtropical. It is allied to the tropical, from which many of its elements have obviously been derived, but the temperate flora of the southern hemisphere occurring to-day in South Africa, Australia, and South America is undoubtedly a very ancient flora. It connects along our great mountain ranges of central Africa with the flora of the Mediterranean region.

The evolutionary history of plants can only be described with any degree of certainty when we know a great deal more, not only about palæobotany, but also about the past history of the world throughout geological time. With the aid of geology, the syntheses can be made more complete. The history of the flowering plants in the world has been mainly a history of response on the part of a widespread, uniform, moist tropical flora to climates which became gradually cooler and drier. In South Africa, owing to its relative geological stability ever since Cretaceous times, the whole process has had a longer time in which to take place, and, apart from certain climatic oscillations of which there is evidence, the process has not been interrupted in any drastic way, as would have occurred if large areas had sunk below sea-level. South Africa throughout the history of the flowering plants has been above the sea and has been joined to the tropical regions to the north. The derivative Karroo flora, therefore, is not only highly evolved but also, in comparison with similar semi-desert floras in other parts of the world, is a rich flora. Those arid plains have been colonised by families such as the Compositæ (regarded by all botanists as the highest of all plants), by relatively advanced members of other circles of affinity, for example, the tribe of Stapelieæ of the asclepiad family, the Mesembryanthemeæ among the Aizoaceæ, and so on. There is a magnificent field here for the study of plant colonisation on a grand scale. A comparative cytological investigation of the numerous species involved should at the same time be undertaken. The importance of isolation in the origination of new forms has long been recognised. Modern work in genetics has shown more clearly the reasons for it. They seem to depend chiefly on the fact that if a new form is prevented from interbreeding with the parent species then the chances of survival are enhanced.

The thing that interests us most for the moment is the undoubted fact that in South Africa we have unequalled opportunities for the study of the facts bearing on such problems. Ecology tends to unify the whole study of botany, and the adoption of the same point of view, with perhaps, to some extent, even the adoption of the same methods and technique, would, I think, tend to do the same thing for other biological sciences.

HUMAN ECOLOGY.

It is a very natural thing to inquire what bearing biological studies of any kind have on the life of man himself. Experience, however, ever since the publication of Darwin's "Origin of Species", and even before that, has gone to show that there is need for caution in applying biological theories to man. The point of view of no single one of the human sciences is broad enough to explain fully why man is as he is and why he behaves as he does. Ecology alone stands apart. The student of man and his works, whether he calls himself archæologist, ethnologist, anthropologist, sociologist, economist, geneticist, geographer, historian, educationist, psychologist, or physician, would do well to become more of an ecologist and try to adopt more and more the general point of view.

Plant ecology may be taken to include plant pathology, since diseases depend on a maladjustment to the environment. So human ecology should also include the study of medical science. Just as plant ecology binds together very effectively all the branches of botany, so human ecology should help to unify—so far as they can be unified—all the separate sciences which deal with man. No one, of course, can attempt to master them all, and no one would be foolish enough to advocate such procedure.

The development of the study of human ecology will probably follow lines similar to those followed by plant ecology. Man reacts to his environment as plants do, but man can control his environment in a way that plants cannot. Nevertheless, the point of view remains the same.

The first phase of human ecology must necessarily be descriptive. The greater the literature dealing with man is in point of bulk, the more need there is for seeking some means of determining the relative value and significance of all its varied content; and that, I feel sure, can be done by applying the test of its value to ecology. It is dangerous to press analogies very far, and it will almost certainly be found in practice that human ecology will not develop on exactly the same lines as plant ecology. The results obtained in the field of plant ecology must be applied with great caution when human communities are studied. At most they may be utilised to suggest hypotheses and useful lines of investigation.

Pioneer men, like pioneer plants, are more plastic in their reactions to the inorganic environment. If the environment is very adverse, complex plant communities cannot be built up; the pioneer stages remain more or less the final stages as well. This is equally true for human communities. The total numbers of pioneers among men as among plants are much smaller than those belonging to later stages of communal development. Pioneers among men, like their analogues among plants, tend to become widely scattered over the world. It is their business to conquer new habitats. They are ready to meet any emergency; they can fight their way through all the varied difficulties presented to them by Nature, but they fail to subordinate themselves to the community as a whole, when that becomes more complex. They remain pioneers and must always strike out along new pathways. They are stifled by the atmosphere of our great cities.

It is unnecessary to carry the analogy any further. It is enough if it has suggested to us that, fruitful as the comparison of pioneer and climax types in the plant world has been, a similar comparison of pioneer and climax types among men (without any reference to plant ecology) may prove even more interesting and valuable. I am aware, of course, that students of sociology have already contributed a great deal to the study of development in human communities: for example, Spencer, Bain, Mill, Hobhouse, McDougall, McIver, Graham Wallas, Westermarck, Saunders, and many others. But few or none of them, so far as I have discovered, have devoted much attention to the advances that have been made in plant ecology, or have adopted the ecological viewpoint. Nowhere could it be better carried out than in South Africa, where we still have almost every possible stage of development of human communities.

A comparison of different stages of development among human communities will probably at the very outset demonstrate quite clearly that our education policy in the past has not been a very wise one. Up to a very few years ago, we were teaching in all our South African schools (whether attended by whites, Indians, natives, or 'coloured' people) more or less exactly the same subjects. There has been and there still is far too much uniformity in our educational system. It is a mistake which is only slowly being put right, and it is doubtful whether it ever will be properly rectified until we carry through more intensive comparative studies of communal development such as I am advocating. In South Africa we are concerned not only with the development of a more or less uniform white race, but the problem is made more interesting and more complicated by the presence of a black race (not to mention the presence of South African Indians as well). The question at once arises as to whether two or more very distinct races can successfully occupy the same territory and, if so, under what conditions. More than ever is caution necessary if we try to apply results obtained in the study of plant ecology to such a problem. If two distinct races of man wish to occupy the same region, whichever of the two is the better suited to the environmental factors will in the long run succeed, while the other will fail.

We often hear the opinion expressed that South Africa is a black man's country. The white man, we are told, can only exist here by virtue of his superior intelligence, which enables him to dominate the blacks and force them to do all the really hard work. Some of the facts already established by plant ecology do seem to have an important bearing on this problem. The climate of South Africa is not tropical. Its vegetation is warm-temperate or subtropical, but not tropical; yet the Bantu peoples of South Africa are a tropical people that left the tropics and migrated southwards not so very long ago.

The idea that the black man is better suited than the white to the South African climate wants very careful consideration. It is true that so long as they do not come into very close and intimate contact with the white man, the black races can occupy and have occupied large tracts of land in South Africa, and that, too, at higher altitudes, such as Basutoland. On the other hand, during times of stress, for example, during the great influenza epdemic of 1918, apparently the black races suffered much more than the white. Those in the best position to know tell us that many diseases, such as tuberculosis, are spreading rapidly among the blacks, with disastrous results. But our information is all vague and unsatisfactory. I am not concerned now with possible explanations of these facts, if they are facts. What I do want to plead for is more organised systematic ecological research. It is surprising, in spite of the great advances in science during recent years, how little really scientific research work has been done on the kind of social problems that concern us most. I have said nothing about the mixed or so-called 'coloured' peoples of South Africa, though most of us probably realise that these present the most important and scientifically the most interesting problem of all, a problem calling for intensive research on ecological lines.

In conclusion, I should like to stress once more the importance of combining different lines of attack on any problem. However valuable specialised studies may be—and that they possess great value no one will deny—they must be combined with a study of each problem as a whole, and that, in its essence, is the ecological method. Of all the sciences which deal with man, modern geography, as it is studied in the best schools, perhaps comes nearest to what I have called ' human ' ecology. It is human ecology, but it scarcely attempts to cover the whole field of what I would include in that subject. It has, however, largely adopted the ecological viewpoint. Similarly, the study of sociology on modern lines, so far as it goes, is pure ecology.

The study of human communities is not the only science which deals with man. Ecology has gone further than sociology in its efforts to synthesise. Human ecology is certainly concerned with social studies and should make full use of all the social sciences, but it should aim also at making equally good use of every other branch of humanistic study, in seeking as perfect an answer as possible to that all-embracing question of how and why man has come to be as he is and to behave as he does.

The Architecture of the Solid State.*

By Prof. W. L. BRAGG, F.R.S.

THE electrostatic basis of the interatomic forces explains in a very elegant way the structures of compounds which contain a number of ions of different kinds. The principle of electrostatic valency in such compounds has been formulated by Pauling.

Suppose a number of ions to come together to form a crystalline solid. The ions are of different sizes, each kind has a characteristic positive or negative charge, and their relative numbers are necessarily such that the whole structure is electrically neutral. How will they arrange themselves so that the electrostatic energy in the interspaces is as small as possible? The governing factors are those of size and charge.

The first feature is that of 'packing'. The ions will fit closely together in order to reduce the interspace with its electrostatic energy. The largest ions are the negative ones, which therefore have the main effect in determining the packing, and the positive ions fit into the spaces in between. To see what arrangement will make the electrostatic energy as small as possible, it is useful to make a picture of the structure in which the electrostatic field is represented by lines of force. These start from the positive ions and end on the negative ions, their numbers being determined by the charges. Our complicated three-dimensional condenser will tend to take up a form such that all lines of force have as short a path as possible.

The result may be illustrated by a structure such as that of beryl, $Be_3Al_2Si_6O_{18}$, shown in Fig. 5. The large spheres are oxygen, and tucked between them one can see silicon (black), aluminium (shaded), and beryllium (white). The oxygens are the negative plates of the condenser, the other atoms the positive plates, and the packing is clear in the diagram. In order that all lines of force may have the shortest path, a certain relation must hold between the electric charges (Pauling's rule). Silicon has a valency 4, aluminium 3, beryllium 2. As shown in the lower part of the diagram, the lines of force Si^{4+} end on four oxygen ions, O^{2-}, thus balancing a charge $-e$ on each. Al^{3+} surrounded by six balances a charge $-e/2$ on each oxygen, and Be^{2+} surrounded by four also balances a charge $-e/2$. The same structure is shown as a skeleton in Fig. 6, and it will be seen that the oxygen atoms (large circles) are of two kinds, and that *each kind has its charge exactly neutralised.* One kind of oxygen is linked to two silicon atoms $(4/4 + 4/4 = 2)$ and the other to silicon, beryllium, and aluminium atoms $(4/4 + 3/6 + 2/4 = 2)$. There is thus local neutralisation of charge in the crystal, and our picture of lines of force is one in which they merely join one atom to the next, and those starting from a positive ion are not forced to wander to distant atoms in the crystal before finding an equivalent negative charge on which to end.

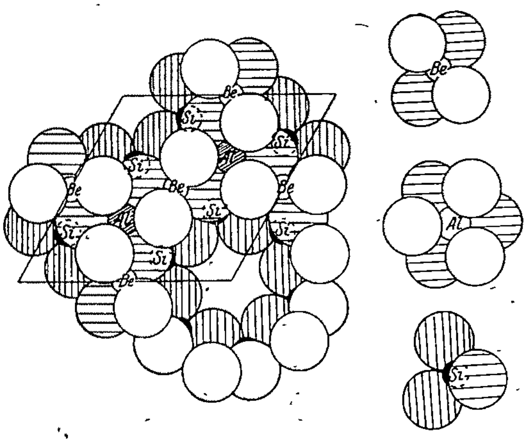

FIG. 5.—The arrangement of atoms in the structure of beryl, $Be_3Al_2Si_6O_{18}$. The large oxygen atoms are densely packed, and the atoms of metal and silicon are in the spaces between them.

It is surprising how the simple rule, with a few hints from X-ray analysis, enables one to build up very complex structures. One stacks the groups together, always obeying the electrostatic rule, and the whole crystal pattern falls into place. It is the electrostatic counterpart to the more rigid rule of valency in organic compounds, when each unit of valency is represented by a single indivisible bond. In the typical inorganic compound the valency can be divided into fractional parts, because it is due to an electrostatic charge, but it still remains true that when these fractional valency bonds between all the atoms are drawn the contributions of the bonds to every atom add up to its valency. As in the case of an organic compound, the formula of an inorganic compound cannot be expressed by a formula merely giving the relative numbers of atoms. The only complete formula is a model of the structure, showing the relationships of its constituent atoms; nothing less can express the valency laws involved.

---

* Continued from p. 212.

Acid radicals, such as $(ClO_4)^-$, $(SO_4)^{2-}$, $(PO_4)^{3-}$, consist of four oxygen atoms surrounding the central atom. The group as a whole has a negative charge, and in a salt these groups are held to the positive ions by electrostatic forces. Now although an oxygen atom can be bound to one sulphur or chlorine atom in this way, forming part of an acid group, it cannot be bound to two without causing an intense localisation of positive charge, because the negative charge of the oxygen atom is more than balanced. Hence these acid groups generally only involve one central atom, such as sulphur or chlorine, rarely two or three. The position is different as regards silicon, for (as in beryl) an oxygen atom common to tetrahedral groups around two silicon atoms satisfies the rule as to equivalence of charge. There is thus no limit to the extent to which silicon-oxygen groups can link up, so that silicon builds a very characteristic class of compounds. The silicon-oxygen tetrahedra can form groups as in beryl, where each unit has the composition Si_6O_{18}. They can link by corners to form endless rows, like long negatively charged chains (Fig. 7). These are attached sideways by positive ions, and form characteristic fibrous structures such as asbestos. They are linked side by side to form extended sheets, as in mica, with positive ions between. When we split a piece of mica we are pulling apart the plates of a condenser. Each acid radical, negatively charged, extends as a sheet, over the whole mica surface.

So far we have considered the crystal as a structure with static equilibrium between the forces of attraction and repulsion. This equilibrium is disturbed when the crystal is elastically strained, or the atoms set in motion by heat vibration.

A very interesting result of X-ray analysis is that we can measure the amplitude of vibration of the atoms at different temperatures, as was first predicted theoretically by Debye, and shown experimentally by Sir William Bragg. A series of such measurements by James is shown in Fig. 8. The X-ray results can be used to make a picture of sheets of atoms in the crystal planes, and the peaks in the diagram represent a cross-section of the crystal density taken normally to certain crystal planes of sodium chloride. The large peak is chlorine, the smaller sodium. As the crystal is warmed, the sharp peaks become broadened, due to the vibration of the atoms, just as the image of an oscillograph is drawn out into a band when it vibrates. A very interesting feature, shown by James, Waller, and Hartree, is that even when the results are extrapolated to the absolute zero, the peaks are not so sharp as they should be according to Hartree's atomic models. The atoms appear to be vibrating even at absolute zero, and calculation shows that the vibration corresponds to the 'zero-point energy' of quantum theory. The extent of vibration is quite considerable at room temperature, and still greater nearer the melting-point. For example, sodium and chlorine atoms at room temperature have an average amplitude of $0{\cdot}22 \times 10^{-8}$ cm., and at 600° C. of $0{\cdot}6 \times 10^{-8}$ cm. as compared with their distance apart of $2{\cdot}8 \times 10^{-8}$ cm.

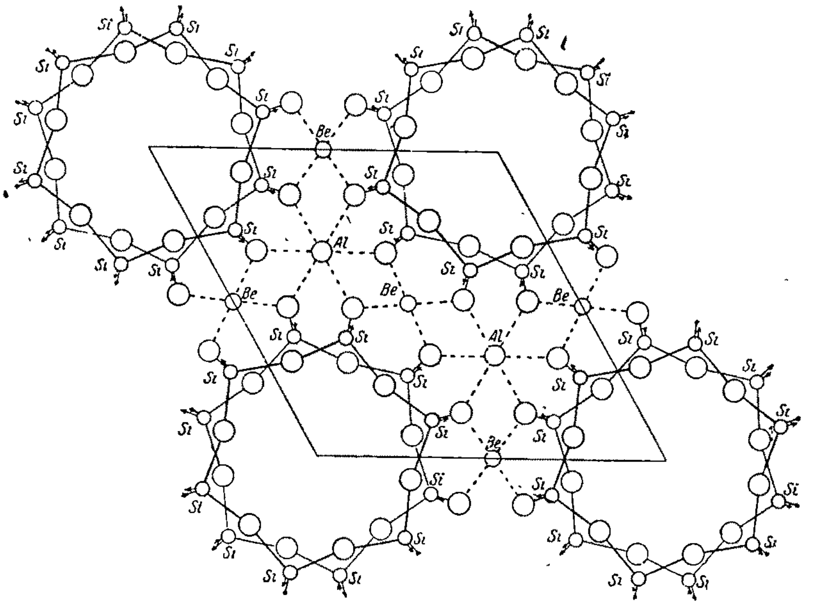

FIG. 6.—The structure of beryl arranged to show the way in which the two kinds of oxygen atoms (large circles) are linked to silicon and silicon, or to silicon, aluminium, and beryllium, in accordance with Pauling's rule.

We may think of the crystal as a three-dimensional spring mattress, the atoms being linked together by springs. Heat causes shivers to sweep backwards and forwards through the solid, displacing the atoms from their normal positions. Two most important properties of the solid are those of thermal expansion and thermal conductivity, and it was first pointed out by Debye that these effects are both paradoxical unless a refinement in considering the repulsive forces between the ions is introduced. If the restoring forces when the atoms are displaced were simply proportional to the displacement, bodies would not expand when heated. In the spring-mattress model, an atom vibrating between two neighbours pushes the one towards which it is displaced and pulls the one from which it is displaced; on the average, such pushes and pulls cancel. But when a departure from the linear relation between displacement and force is taken into account, the pushes are increased and the pulls weakened. Each vibrating atom, then, helps to force the whole structure apart.

Thermal conductivity, in the case of those solids which are not electrical conductors, depends upon transference of atomic vibrations from hot to cold regions. The heat motion consists of waves, and if these waves traversed in the body quite independently of each other, any agitation at one end of the body would immediately rush to the other at the speed of elastic waves in the body. Hence thermal conductivity should be almost infinitely great. Actually the different wave-trains are not independent, but influence the motion of each other. They therefore scatter each other, and the advancing region of wave agitation has to fight its way towards the cold end of the body through a fog of waves which it itself creates.

The question of the outer form of a crystal, the relative growth of its crystal faces, falls in another category. The lattice theory can tell the relative surface potential energy of the various crystal faces, and the form of the crystal should be one which makes the total surface energy a minimum. However, one can scarcely expect successful prediction in this case, when we know how greatly crystals vary in form when grown under different conditions. Small traces of foreign bodies in the solution or liquid entirely alter the crystal form. The energy of the surface is too small compared with that of the crystal as a whole, and reacts too sensitively to adsorbed layers.

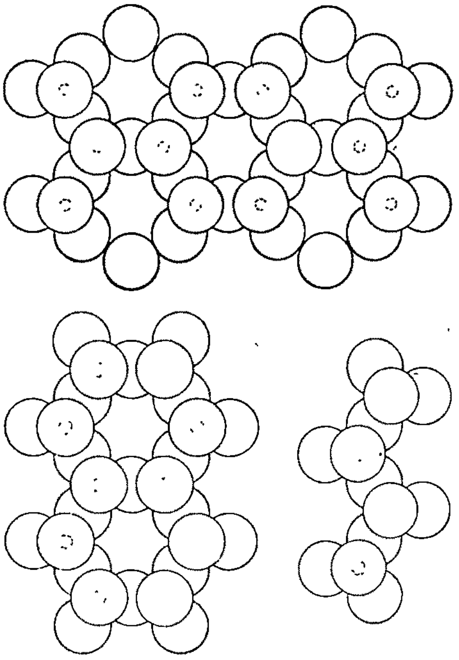

Fig. 7—Chains and sheets of silicon-oxygen groups in the silicates Silicon, shown as a small circle, always lies between four oxygen atoms and the tetrahedral groups are linked by sharing oxygen atoms.

In the explanation of the tensile strength, as ordinarily measured, the lattice theory breaks down entirely. Rocksalt should be rather stronger than the strongest steel, whereas Joffe has shown that it breaks under a stress only 1/500th that calculated theoretically, and explains this by supposing a crack always starts at a weak place and the crystal tears rather than breaks. An initial break at any point in a crystal concentrates the strain upon the neighbouring regions, which break in their turn. In order to get a body which has a high tensile strength, it must be ensured that, when at any point a break does occur, the resulting increase of stress is distributed widely. Tensile strength is, in other words, not so much a question of strength of bonding in the direction of the stress, as of weakness of bonding at right angles to it. The strength of a sheet of mica, or a fibre of asbestos, is due to the very feeble forces with which the sheets or fibres are attached to each other laterally, so that if one fibre gives, the additional stress is shared by the rest of the bundle of fibres.

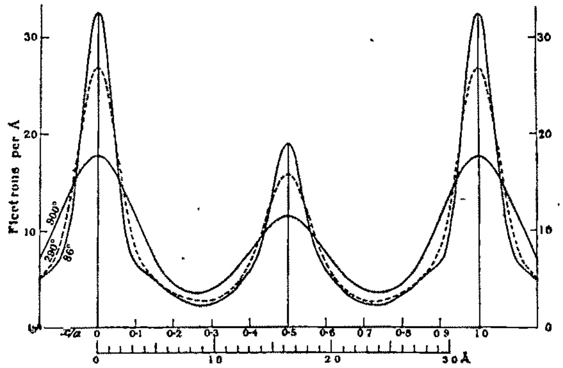

Fig 8.—The vibration of the atoms when sodium chloride is heated. The octahedral crystal planes consist of alternate sheets of chlorine and sodium atoms, represented in the figure by the large and small peaks respectively. As the temperature is raised, the sheets become broader and more diffuse owing to thermal movement. (James and Firth.)

The tensile strength is one example of many in which the behaviour of the real crystal, built of a number of crystalline elements, differs from that of the ideal perfect crystal and requires a new type of treatment. X-ray analysis has always shown that actual crystals are composed of a number of small blocks, or ' mosaic ' as Ewald terms it, of crystals which are nearly in the same orientation, but not quite. There must be a misfit at the boundaries between these blocks. For some crystalline properties, such as heat of formation or double refraction, the mosaic structure has no influence. For other properties it is all-important, and tensile strength appears to be such a property. Smekal has always insisted on the important difference between the ' ideal ' and ' real ' crystal, and believes many properties to be essentially dependent upon it.

Thus, when one considers the properties of the solids which are of technical importance, in contrast to those of the ideal crystal, little success in exact interpretation can be claimed. However, the knowledge of atomic arrangement has performed a service, the usefulness of which is not so obvious, but is yet very great; it has provided a new language, or series of conceptions, in which to express the vast amount of empirical knowledge about the behaviour of materials which has been accumulated.

News and Views.

The subject of noise and its measurement, dealt with by Dr. G. W. C. Kaye in his recent Royal Institution discourse, which forms our supplement this week, is one of great practical importance and wide interest. It is becoming increasingly apparent that excessive or particularly irritating noise is injurious to health, happiness, and working efficiency. Laboratory measurements have shown that even during sleep sufficiently deep to render the sleeper unconscious of any sounds, response to such sounds as are made by the early morning milkman is readily detectible. There are numerous practical difficulties in the quantitative measurement of noise, since acoustical, psychological, and physiological factors are all concerned. A general survey of the methods at present in use is given by Dr. Kaye. The results gathered from several independent sources deal with all types of noises, from the whispering human voice, the crying of twins, and the applause at Lindbergh's reception in New York, to transport noises, the roaring of lions, and the sounds of Niagara Falls.

It is noteworthy that increased speed of transport is only obtained at the cost of increased noisiness, the average loudness levels in decibels above threshold inside various vehicles being for a recent type of bus or a saloon car or express train about 60, whilst for aeroplane cabins the value is about 100. Much of the noisiness of modern transport could only be reduced by redesign of the machinery involved, and it is unfortunate that the silence of the exhaust of the luxury motor car is obtained only by a certain loss of engine efficiency. For this reason, the same methods could not easily be used to reduce the machine-gun-like noises of the motor bicycle exhaust. The absolute amount of sound energy lost by even the noisiest of machinery is negligibly small, and quieter machinery is therefore only more efficient because of better mechanical design and not because of absence of sound-energy losses. From noise measurements made inside buildings, it is evident that stillness could be much more readily obtained in the Victorian home with its general solidarity, heavy hangings, and absence of loud speaker and gramophone, than in the modern ideal home with its thin walls and flimsy hangings.

On Aug. 20 occurs the centenary of the birth of the eminent Austrian geologist Eduard Suess, who was born at No. 4 Duncan Terrace, Islington, a house which now, thanks to the action of Dr. F. A. Bather, bears a commemorative tablet. The son of a German merchant then resident in England, but who afterwards lived at Prague and Vienna, Suess was educated in the University of Vienna, and became an assistant in the Imperial Museum. At the age of twenty-six years he was made an extraordinary professor in the University, and ten years later was appointed to the chair of geology, a post he held until 1901. A most successful teacher, he counted among his pupils Mojsisovics, Fuchs, Waagen, Penck, and Neumayr, who became his son-in-law. In addition to his academic posts, he held seats in the Municipal Council of Vienna and the Diet of Lower Austria. It was largely through him that Vienna obtained an adequate water supply. He was chosen president of the Academy of Sciences of Vienna, was elected a foreign member of the Royal Society, and received the Copley Medal, while the Geological Society awarded him its Wollaston medal. He was included among the Scientific Worthies whose work has been reviewed in Nature, an account of his life being given in our columns in 1905 by Sir Archibald Geikie. Suess died at Vienna on April 25, 1914.

Much of the earlier work of Suess dealt with the geology of the Vienna basin and the Alps, but he will always be remembered for his monumental work, "Das Antlitz der Erde". Setting himself the task of taking a comprehensive survey of all that had been accomplished in elucidating the geological structure of every part of the globe, he published the first part of his great book in 1885, the second in 1888, and the third in 1901. "The supreme scientific success attained by this great work", says von Zittel, "was a tribute to a work accomplished with the highest bibliographical skill and literary finish, the fullest geological and geographical knowledge, a convincing array of scientific facts that never fail to suggest an endless reserve in the background, and, above all, a calm, judicial, elevated tone of inquiry which the end of the nineteenth century may well feel proud to have witnessed and carried with it into its boasted wealth of scientific enlightenment." "Das Antlitz der Erde", it has been said, takes its place as a scientific classic beside Hutton's "Theory of the Earth" and Lyell's "Principles of Geology"; while of Suess, Prof. J. W. Gregory remarked, at the unveiling of the tablet in Islington, that "he ranked as the greatest original force in geological philosophy of his time".

One of the recommendations of the Committee on National Expenditure was the abolition of the Empire Marketing Board. The Board's report for 1930–31, which has recently been published (H.M. Stationery Office, price 1*s*.), forms an adequate comment on which we need not enlarge. In spite of the world-wide economic depression, record imports for sixteen commodities from the Empire into Great Britain have been established, the increase being attributed largely to the greater attention paid by the producers to grading and marketing and to the closer contact attained between the home traders and the overseas producers. Although its activities are developing considerably, the methods of the Board have been similar to those in previous years. Economic investigations and market inquiries have been extended, and grants for research work both in Great Britain and overseas are being continued. A complete list of the latter is appended, with a short account of the work under investigation in a number of cases. The importance of collecting and disseminating information regarding the supplies of Empire and foreign commodities available is fully recognised, and the issue of the weekly notes for fruit and dairy produce has been extended to include figures for the quantity of butter in cold storage, thus making a study of the consumption of imported butter possible for the first time. Two further reports on economic investigations, entitled respectively "The Marketing of Cheese" and "The Preparation of Fruit for Market", have been published, bringing the total number of this series up to twenty-five, and statistical surveys of world production and trade in beef and wool, similar to those already issued for oranges and cocoa, are nearing completion. Publicity has been obtained in a variety of ways, and definite success has attended the experiment of the opening of two shops in which samples of Empire produce are sold, under conditions which secure the goodwill and co-operation of the traders. The report concludes with a list of the publications of the Empire Marketing Board and the Imperial Economic Committee.

THE use of electricity to heat the soil around plants so as to force their growth has been experimented with successfully by engineers connected with the Southern California Edison Company. The main factor to which the success of the experiment is due is that the product can be placed on the market early, so that the price is three or four times greater than later on. When all the crops mature at the same time, the market is flooded and the price falls. Two exactly similar plots of ground were taken. One had insulated wires running through it about four feet apart and at a depth of eight inches. The current in the wires was regulated by a thermostat so as to maintain a temperature of about 70° F. Current flowed on an average two hours out of every five. The other plot was not electrically heated but was prepared in exactly the same way. Cucumber seeds were planted in both plots, in rows about four feet apart. It was found that more than one half of the crop in the wired portion had matured and been marketed before the first cucumber had reached maturity in the unheated plot. The net revenue obtained from the electrically heated plot was about £20 greater than from the other. Details of the experiment are given in the *Electrical Review* for Aug. 7.

MARCONI'S Wireless Telegraph Co., Ltd., has acquired from the British Air Ministry the full rights and drawings for the design and erection of radio beacon stations of the rotating type. Marconi fixed beacon transmitters have been installed at important coastal points in many parts of the world as an aid to maritime navigation. The company will now be able to provide for aerial navigation as well. Both kinds of navigation will doubtless benefit by having alternative beacons. The experimental rotating beacon stations at Orfordness, Gosport, and Farnborough have been reported on favourably. A special feature of the rotating beacon system is that it requires only an ordinary radio receiver and a stop-watch to enable a ship or an aircraft to take its bearings. It is likely, therefore, that the system will prove valuable in extending the use of radio navigation even to quite small ships. The beacon makes use of a vertical closed aerial rotating at a uniform speed of one revolution in 60 seconds. The radiation from such a loop is a maximum in the plane of the loop, and zero, or a minimum, at right angles to that plane. For the calculation of bearings, two distinctive signals—a 'north signal' and an 'east signal'—are transmitted at regular intervals as the aerial rotates. The normal method of observation at the receiving station is to start a stop-watch at the moment the north signal ends, after which the time taken for the zero signal to be reached indicates the bearing of the observer from the beacon. If the observer is due north or south of the beacon, he may not be able to read the north signal, owing to the directional effect of the transmission. In this case the east signal is taken as the starting point. The number of seconds from the reception of the signal to the reception of the minimum signal gives the bearing in degrees. It seems likely that when navigators have become accustomed to radio beacons, it will be possible to dispense with several lightships.

FOLLOWING on the excavation of a seven-roomed house, later converted into baths, at North Wharnborough, Hampshire, which was discovered in 1929, a building of considerable size has been brought to light, as is announced in the *Times* of Aug. 10, which may furnish much-needed evidence bearing on the rural organisation of Roman Britain. The buildings are situated only 8½ miles from the city of Calleva Atrebatum (Silchester); but they lie on no known Roman highway. The larger structure, like the smaller, would appear to have served two purposes; for at some time in its history it was converted by the erection of interior walls of wattle and plaster, relatively less substantial than the solid outer walls, into a system of cubicles, probably intended for farm labourers. Four buildings outside the south-west outer wall are probably stables. Coins, all belonging to the Constantine period or later (A.D. 306–381), were found. Presumably Silchester served as the market town for the villa. This is in some measure supported by the discovery of a potsherd inscribed 'Peregrini'. There were two potters of the name of Peregrinus, one from Southern Gaul, of the age of Domitian, A.D. 81–96, the maker of ware which has been found on several sites in Britain, and notably at Silchester.

THE academic study of comparative law is, as a rule, confined to codified law. This is due in part to the fact that material for study of non-codified law has not been available. In the nineteenth century opportunities for collecting data were neglected, as it was considered inevitable that such systems were destined to disappear. The event has proved that this view was erroneous; at the present day one half the globe is under the jurisdiction of Oriental and tropical customary law. Further, juridical science is coming to recognise more and more the importance of the non-codified systems of law. The whole subject, however, is in need of organisation before systematic

Noise and its Measurement.[*]

By Dr. G. W. C. KAYE, O.B.E., Superintendent, Physics Department, National Physical Laboratory.

FREQUENCY AND INTENSITY RANGES OF THE EAR.

AS is the case in many branches of science, the physics of acoustical research owes its present facility and exactitude largely to the development of electrical methods of measurement. The key lay in the invention of the electronic valve, and to this the subject owes an impetus which it had long needed.

Before we pass on to the question of noise measurement, we shall be well advised to review the relevant physical facts about the ear, which is of course the ultimate critic in matters of noise. The foundations of the subject rest largely on experiments with pure notes, and here it should be recognised how greatly our present knowledge of both hearing and speech is due to the noteworthy investigations of Dr. Harvey Fletcher and his colleagues at the Bell Telephone Laboratories in New York.

With reference to frequency, the average ear can perceive a range of frequencies from about 20 to 20,000 cycles per second, the upper limit declining with advancing years. In the various practical developments of acoustics, however, attention is largely restricted to the ranges 50 to about 5000 for speech, and 35 to 7000 for music.[1]

As regards intensity, it has been shown by Wegel and others, from experiments on pure notes, that there is a certain minimum amplitude for each frequency below which the average ear fails to detect the note. Moreover, the ear is much more sensitive to notes of medium pitch than to higher or lower notes. The threshold or lower limit of intensity passes, in fact, through a minimum at about 2000 cycles per second as we steadily change the frequency.

Similarly, there is a maximum amplitude peculiar to each frequency, above which the ear no longer functions—hearing is subordinated to a tickling sensation or even actual pain. Again the ear shows to advantage in the middle of the range (about 500 cycles per second), and so the upper limit of intensity or threshold of feeling passes through a maximum as we progressively vary the frequency.

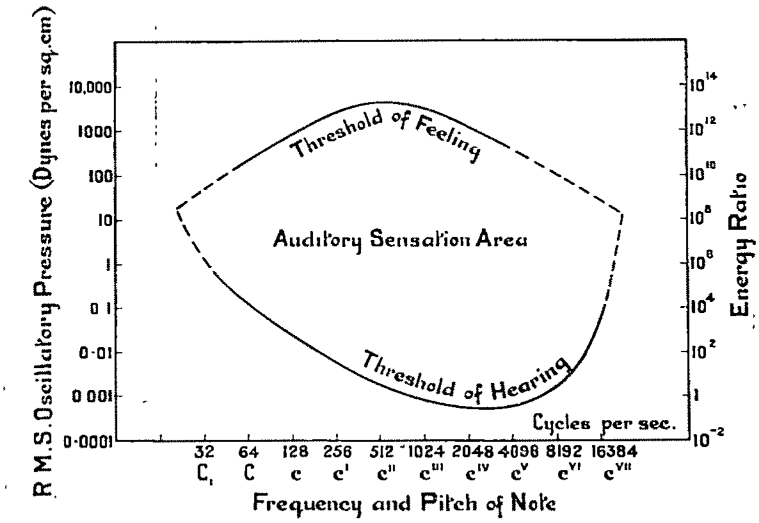

FIG. 1.—Average area of normal hearing, showing auditory ranges of frequency and intensity. (From Fletcher's "Speech and Hearing".)

Fig. 1 shows the auditory sensation area for the average ear as determined by Fletcher and Wegel. The boundaries are constituted by the two threshold curves, the dotted portions being those which are difficult to determine. We see that the range of audibility passes through a maximum (at about 1000 cycles per second) as the frequency is varied, and is greatly reduced towards each end of the musical scale. This maximum range corresponds to about a million million-fold variation in power, or a million-fold variation of acoustical pressure from about, say, 0·0005 to 3000 dynes per sq. cm. We note also in the case of very high and very low notes the great intensity that is essential for audibility and how restricted the range of audibility is. A familiar illustration is the sound from a 32-ft. organ pipe, which one feels rather than hears.

---

[*] From a Friday Evening Discourse given at the Royal Institution on May 8.

THE MATCHING AND MASKING OF SOUNDS.

As regards the matching of sounds, it is found that the average ear can recognise under very favourable conditions a 10 per cent difference of energy when two pure notes of medium loudness are sounded alternately without break. This figure is more than doubled if there is an interval of silence between the two notes of so little as half a second. Under ordinary conditions, however, the smallest average change in energy level detectable by the normal ear is of the order of 26 per cent for sounds of medium intensity and frequency. The figure is greater for feeble sounds, and less for very loud sounds. The value is also greater for very high or low frequencies than for the middle of the range.

From the fact that it is a percentage increase rather than an additive increase of energy which the ear associates with a change of loudness, it is evident that, while the steps in the scale of sensation of loudness advance arithmetically, the physical intensities advance geometrically, the relation thus resembling the logarithmic scale of powers of a slide-rule. Here is, then, another illustration of the Weber-Fechner law—the physiological effect is roughly proportional to the logarithm of the energy producing the stimulus.

Kingsbury has carried out experiments on the matching of pure tones to determine the relation between the physical intensity and the aural loudness for different frequencies. These experiments indicate that for frequencies between about 700 cycles and 4000 cycles per second the relation between loudness and intensity is independent of the frequency. For notes of lower frequency the loudness increases proportionately more rapidly than the intensity. Kingsbury's results are set out in Fig. 2, which shows a number of equal loudness contours superposed on the auditory sensation area. As will be seen, these contours are roughly parallel to each other for medium frequencies above about 700 cycles per second.

An experimental illustration based on such loudness contours is to operate a pure sound at constant intensity, and gradually increase the frequency, when the loudness will be heard to pass through a maximum at about 2000 cycles per second. This is evidenced by the track of the horizontal line in Fig. 2 at a level of about 0·1 dyne per sq. cm.

The masking of one pure note by another is usually measured by the extent to which the threshold of audibility of the masked note is raised. In general, a particular note is masked (1) most readily of all by another of approximately the same frequency; (2) more readily by a note of lower frequency than one of higher, at any rate for loudnesses about and above speech level.

The position is not so simple with loud complex sounds such as noises, as the masking may be confused by other factors such as the masking of the individual components and the formation of subjective tones (see Fletcher's "Speech and Hearing").

THE DECIBEL.

We are now aware of the area of auditory sensations which we have to measure, and we have to decide what is to be our 'yardstick' or 'degree'. Our task is to try to correlate aural loudness with physical intensity or energy; and already we have seen that while the sensation of loudness advances, as it were, by simple addition, the energy level increases by leaps and bounds on a scale which extends over almost astronomical magnitudes. This is a cumbersome relation, and it is clear that there will be a real convenience in adopting a scale of ratios of energy for our purpose. A similar need which arose in telephone engineering was met by the introduction of the 'bel', a name chosen in honour of Alexander Graham Bell, the inventor of the telephone. One 'bel' expresses a tenfold increase of power or energy; in other words, two intensities in the ratio $r : 1$ differ by ($\log r$) bels.* It has been generally agreed to adopt the bel for acoustic requirements also, or rather the 'decibel' (db.), since the bel is a little too large for the purpose. We thus have the following tabular relation:

Ratio (r) of Intensities.	No. of Decibels (10 log r).
1	0
10	10
100	20
1,000	30
10,000	40
	—
10^{13}	130

It will be realised that this scale of decibels is in no sense physiological but is based wholly on intensity as measured by physical methods. The scale has, however, the specific advantages (1) of being a rough fit with the aural scale of loudness sensation; (2) that experiment shows that the decibel, as above defined, corresponds approximately to the least perceptible change in loudness of a sound of medium loudness under average conditions. In actual fact, the loudness step in question is sometimes a little more and sometimes a little less than a decibel (ranging from 0·2 db. to 9 db.), according to the frequency and the location in the auditory sensation area.

---

* Logarithms are to base 10.

We are now in a position to set up a definition of the sensation level of a pure note of specified frequency in physical terms. Our 'degree' will be the decibel, our 'zero' the threshold of audibility for that frequency, and the sensation level of a pure sound may accordingly be defined as the intensity in decibels above the threshold of audibility of that frequency.

On this basis experiment shows that, for pure sounds of medium frequency, the range of audibility between the thresholds of hearing and feeling is covered by about 130 decibels. This figure is rather less for high and low frequencies.

The position, however, is not so straightforward when we come to the broader question of comparing the loudness of pure sounds of different frequencies. We find at once that there is no simple relation of wide application between physical intensity and loudness. Two pure sounds of different frequencies do not in general produce the same loudness sensation, even if (*a*) their physical intensities are equal, or (*b*) their physical intensities bear the same ratio to their respective threshold values, that is, if the sounds have equal sensation levels. Further, if the intensity levels of two pure sounds of different frequencies which appear equally loud are increased by the same amount, the sounds will not in general remain equally loud.

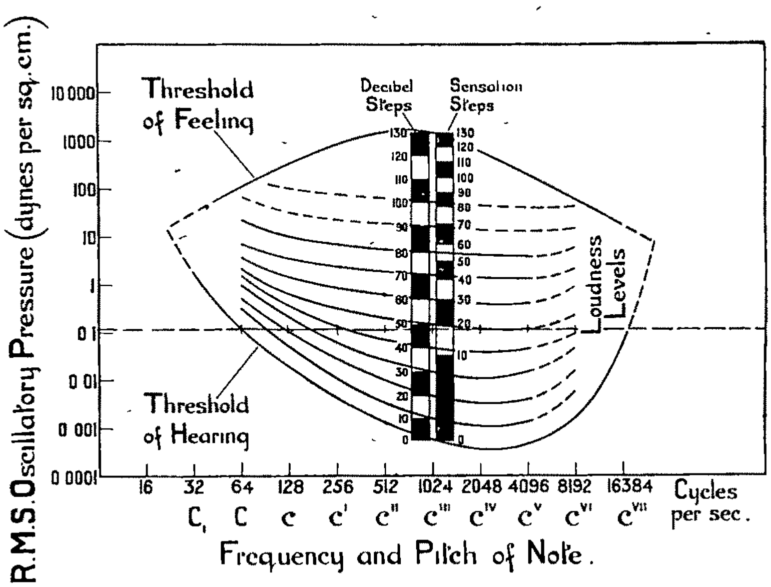

FIG. 2.—Auditory sensation area, showing equal loudness contours; also decibel 'ladder' and sensation-step 'ladder' for a frequency of 1000 cycles per sec.

It follows that, in the case of sounds of different or mixed frequencies, neither the physical intensity level nor the sensation level can be used as a measure of loudness. In the circumstances, we have to adopt an arbitrary scale as a practical standard, and a suitable one for the purpose is the sensation scale of a pure note having a frequency in the region of 1000 cycles per second. Then the loudness of any sound, whether pure, or a mixture such as noise, is defined as the sensation level (expressed in decibels above the threshold value) of the standard note which appears equally loud to the ear. It may be mentioned that the zero or threshold value of a 1000-cycle scale corresponds to a pressure of about 1 millidyne per sq. cm.

It should be reiterated that such a standard scale is quite arbitrary, and that equal increments on the scale do not in general approximate very closely to an equal number of sensation steps. For example, in the case of the 1000-cycle scale, the step from 0 to 10 decibels corresponds roughly to about 1 perceptible gradation of loudness under average conditions, the step from 50 to 60 contains about 10 gradations, and the step from 100 to 110 about 15. In other words, we may ascend the range of physical intensity lying between the two thresholds, either by the decibel ladder with equally spaced rungs, or by the sensation-step ladder with rungs first widely spaced and afterwards more narrowly though more evenly spaced (see Fig. 2).

It may be added that, in adopting a practical scale of loudness, some latitude is possible in the choice of the standard frequency, in view of the fact that for medium frequencies above 700 cycles per second there is a constant relation between loudness and sensation level. For example, the standard frequency chosen for much of the work at the National Physical Laboratory is 800 cycles, while, in the United States, 1000 cycles has been largely used.

SPEECH AND NOISE.

The masking effect of a background of noise on the ease of conversation is one of primary interest. Conversation begins to be difficult when the background of noise reaches 70-80 db., while at 90 db. conversation, even by shouting, is virtually impossible.

It should be remembered that the greater part of the energy of the human voice is in the low-frequency region. Some sixty per cent of the energy lies in frequencies below about 500 cycles per second, and about eighty-five per cent below 1000 cycles per second. It is known, however, that the intelligibility of speech rests largely on the high-frequency consonants (say above 1000 cycles per second) rather than on the low-frequency vowels (say 120 cycles for the male voice and 240 cycles per second for the female), despite the fact that the low-frequency components carry the major part of the energy.

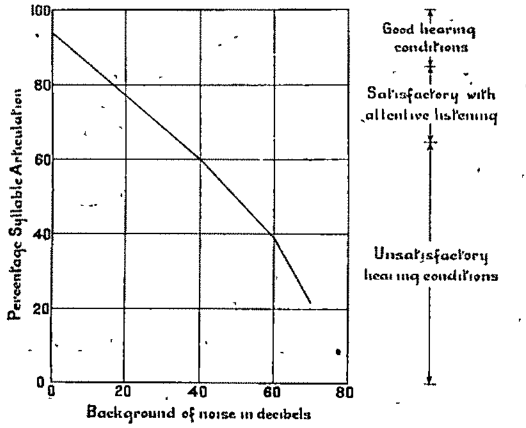

FIG. 3.—Effect of extraneous voice on intelligibility of speech of normal loudness (50 db.). (Knudsen.)

Davis and Evans at the National Physical Laboratory have observed that conversation in an enclosure is facilitated if high-pitched noises are excluded from without. It is fortunate that such notes can be more readily excluded than low notes, and particularly so where limits are set to the massiveness of the walls of the enclosure, as in an aeroplane cabin. Furthermore, such high notes as gain-entrance are more readily absorbed by mounting absorbent on the inner walls.

As regards the effects of noise on the hearing of speech, Knudsen found in 1925 that, if the interfering sound is a pure note at about speech-level, the interference with speech is almost independent of frequency, but that for greater intensities low-pitched notes interfere more than high. He also states that the interfering effect of noise is greater than that of a pure note whatever the pitch. Fig. 3 (due to Fleming) summarises Knudsen's results on the effect of extraneous noise on the intelligibility of speech as interpreted by articulation tests with speech of normal loudness (50 db.). As will be seen, even a little noise affects speech reception adversely, while a noise level of some 30-40 db. reduces the intelligibility by an intolerable amount.

ANNOYANCE AND NOISE.

The association of annoyance and noise has recently been the subject of experiment. Precise measurement could scarcely be expected perhaps, but it is clear that both frequency and loudness are among the factors which play a part. As to pitch, it is probable that the majority of people find shrill sounds more offensive than low. They find, for example, the high-pitched motor horn, to the staccato use of which the Paris taxi-driver is so addicted, more irritating than the lower pitched horn which is generally used in England. This impression is confirmed by the work of Laird and Coye, who found that annoyance is a function of both loudness and pitch, high pitches being intrinsically more annoying than low or medium pitches, and very loud high pitches being especially irritating. In the case of pitches below about five hundred cycles per second the annoyance was, however, purely a matter of loudness. In this connexion it is of considerable interest to note that the range of pitches which man normally employs in his own speech appears to be the least annoying to him. The irritation produced by certain tenor and soprano voices is claimed by Laird and Coye as being in harmony with their findings.

The annoyance produced by complex noises such as those resulting from motor horns appears to be largely influenced not only by sheer loudness, but also by the presence of strong high-frequency components as well as by strong inharmonic components.

ABSOLUTE MEASUREMENT OF ACOUSTICAL ENERGY.

A standard method of measuring the absolute energy of waves in general is to absorb them completely in some suitable material and measure the amount of heat generated. But, even if such absorption were possible in the case of sound waves, the absolute amounts of energy in speech and most other sounds of everyday experience are so small as to be on the borderline of the capacity of the most sensitive heat-measuring instruments we have. For example, the average speech power of the conversational voice is about ten microwatts. This value rises to about a thousand microwatts for the shouting voice, falls to 0·1 microwatt for the quietest speech, and to about 0·001 microwatt for the softest whisper. To take an illustration, a Final Cup-Tie crowd of 100,000 at Wembley Stadium all talking continuously and rather loudly would provide as much speech power as would, if converted, light a small electric lamp throughout the game. Alternatively, by the end of the match the acoustical energy expended would have been sufficient if transformed into heat, to boil enough water to make one cup of tea. An especially enthusiastic crowd which shouted vigorously all the time might similarly manage ten cups—perhaps enough to fill the Challenge Cup itself!

There are, however, one or two outstanding examples of acoustic disturbances in which substantial amounts of energy are involved. Measurements in New York on ships' sirens have shown a power-level of about 6 microwatts per sq. cm. at a distance of 115 feet, so that the total acoustic energy emitted by the siren would appear to be about ⅛ h.p.

For sounds of ordinary magnitude, however, it is clear that the outlook for thermal methods of measuring acoustic energy absolutely is not promising, and we must turn to some other property of the sound waves. The oscillatory variation of the air pressure in the track of the advancing sound wave, the accompanying minute changes of refractive index and of temperature, the velocity of the oscillating air particles, and the radiation pressure exerted on a reflecting surface have all been employed. A conversational sound corresponds to an alternating pressure (*R.M.S.*) of about 1 dyne per sq. cm.,* in other words, to a pulsation of 1 millionth part of the atmospheric pressure. The change in refractive index for such a pressure variation is about one part in a thousand million, the temperature variation about 1/1000° C., the particle velocity of the air about 1/40 cm. per second, and the radiation pressure only some 10^{-11} of an atmosphere. The corresponding power is about 1/1000 microwatt per sq. cm., it being recalled that the power (or energy) varies as the square of the pressure and the amplitude.

For the purposes of absolute measurement, we are led to look for a measuring instrument which will give readings independent of both frequency and wave form of the sound. One of the most convenient is the Rayleigh disc, which measures the air or particle velocity. It is, however, a fragile instrument, to be regarded rather as an ultimate standard of reference, the use of which is necessarily restricted to the standardising laboratory. More convenient and robust instruments are essential for practical purposes, and recourse is usually had to electrical microphones, preferably of a non-resonant type. These translate acoustical oscillations into electrical oscillations which are amplified by a suitable valve amplifier, and so can be conveniently and accurately measured provided proper precautions are taken.

A variety of other devices, many of them of the mechanically resonated type, have also been proposed from time to time as sound measurers or recorders, but for a number of reasons their use has been almost entirely discontinued in favour of electrical microphones, particularly those of the condenser or electrostatic type.

The condenser microphone consists essentially of a metal diaphragm tightly stretched and mounted parallel and very close to a metal plate, the gap being only about 1/1000 inch. The thin section of air enclosed adds materially to the stiffness of the stretched diaphragm so that its resonant frequency is very high—usually above the normal range of acoustic frequencies. To the condenser formed by the plate and diaphragm a potential difference of about 200 volts is applied through a high resistance. Sound waves incident on the diaphragm cause it to vibrate, resulting in variations of the capacity of the condenser which, in turn, produce across the series resistance an alternating E.M.F. which can be readily valve-amplified and so measured by means of a rectifier (such as a thermojunction) and microammeter. Alternatively, the wave form may be examined by a cathode ray oscillograph. The condenser microphone, though somewhat insensitive, enjoys the advantage of a fairly uniform response over the acoustic range of frequencies, and thus provides a useful standard instrument, which can be calibrated in absolute units.

MEASUREMENT OF NOISE.

It was, I think, Lord Kelvin who said that once we find out how to measure a thing, we begin to learn something about it. As regards noise, however, it is evident that the question of its measurement is one of some complexity, involving not only physics but also physiology and psychology. Nevertheless, so far as the physical aspect goes, it is clearly desirable that there should be a consensus of opinion on the choice of a system of physical quantities. They should be preferably of an absolute character, so as to assist, *inter alia*: (*a*) in translating vague aural judgments and comparisons into facts and figures; (*b*) in elucidating the causes and characteristics of noises; (*c*) in comparing the results of different investigators; and (*d*) in setting up such arbitrary standards of noise as may be desired in the light of social, technical, or legal requirements.

---

* It is estimated that the street noise of New York exerts an average pressure of about 5 dynes per sq. cm. and may even reach 20 dynes per sq. cm.

The practical measurement of noise usually comprises one or more of the following operations:

(1) The physical measurement of the 'over-all' power or energy-content of the noise, the result being ultimately expressible in absolute units (for example, dynes or microwatts per sq. cm.).

(2) The physical analysis of the noise into its spectrum of frequency components (cycles per second). This is often most illuminating in tracking down the sources of individual components, particularly of machinery noises.

(3) The physical determination of the wave form of the noise, though this is often difficult to interpret and to utilise quantitatively, particularly if the noise is aperiodic.

(4) The aural measurement in some accepted unit of the loudness of the noise, or, in other words, the evaluation of the 'noisiness' as perceived by the ear—the physiological arbiter of noise.

PHYSICAL MEASUREMENT OF NOISE.

We have already discussed the measurement of sound energy by means of the condenser microphone and amplifier. The amplified current is connected either to a rectifier and microammeter (graduated in decibels if desired) for measurement purposes, or, alternatively, to a cathode ray oscillograph if it is desired to examine the wave form. In view of the fact that the microammeter readings are measures of physical intensity and not of loudness (owing to the selective sensitivity of the ear to pitch), a frequency-weighting network is sometimes interpolated in the circuit with the object of approximating the results more closely to the average aural interpretation. The weighting curve may conveniently be chosen for a loudness corresponding to that of a 1000 cycle-tone at 30-40 db. above the threshold of audibility.

If it is desired to analyse the noise, this may be effected by incorporating electrical tuning or band-pass filtering devices into the circuit and so determining, in turn, the amount of energy associated with individual components or bands of frequency. It is not always possible, however, by such means to get sharp selectiveness, but, in any event, we have to recognise that as yet our knowledge is not sufficiently general to enable us to correlate exactly the over-all loudness of a noise with the energy or loudness of its constituents.

SEARCH-TONE METHODS OF NOISE ANALYSIS.

The question of the practical analysis of noises which are reasonably periodic has been much facilitated by the introduction of search-tone methods, which in general enable sound to be more conveniently analysed and with higher selectivity over a wide frequency range than is possible by the method of tuned circuits.

When search-tone methods are employed, the noise to be analysed is received in a microphone, the current of which is amplified and 'mixed' in a valve-rectifier or modulator with that of a pure search-tone of constant intensity and variable known frequency from a heterodyne oscillator. As a consequence, the modulated current contains not only the search-tone, but also the summation- and difference-tones formed from the search-tone and the various individual constituents of the noise. For example, if the frequency of the search-tone is S, and that of a particular constituent of the sound is C, the frequencies of the summation- and difference-tones so formed will be $(S+C)$ and $(S-C)$ respectively.

One way of revealing the existence of either of these tones is to apply the modulated current to a highly selective mechanical resonator, such as a steel bar capable of vibrating longitudinally. Thus, as the search frequency is varied continuously, the bar will begin to resonate whenever either $(S+C)$ or $(S-C)$ becomes equal to the natural frequency of the bar. As we know S, we can evaluate C; and further, the degree of response of the bar, which is observed by suitable means, will give us a measure of the energy in the constituent in question. In practice, S may range from, say, 11,000 cycles to 16,000 cycles per second, while the natural frequency of the bar may well be of the order of 16,000 cycles per second for the summation-tone method and 11,000 for the difference-tone method.

Grützmacher uses, instead of a mechanical resonator, a low-pass filter arranged to transmit frequencies less than about 30 cycles per second. It follows that, in the great majority of cases, both the search-tone and all the summation-tones are ruled out, and only those difference-tones with frequencies less than 30 cycles per second will pass the filter and be recorded by an appropriate amplifier and detector. Thus, as the search frequency is continuously varied, the detector will only respond when the frequency is within 30 cycles per second of that of a constituent tone of the noise. The magnitude of the detector reading can be made to afford a measure of the intensity of the component in question. In the outfit at the National Physical Laboratory the frequency of the search-tone is varied from, say, 30 cycles to 10,000 cycles per second by the rotation of an air condenser through 180°.

AURAL MEASUREMENT OF NOISE.

As we have already seen, if we are provided with a standard pure note of medium frequency (above 700 cycles per second) the loudness of which is variable at will over a range which has been calibrated by physical means, then we can evaluate by aural matching or equality the loudness of any other pure note or, in general, of any complex note. Alternatively, measurements may be made of the loudness of the standard note which is just masked or drowned by the sound to be measured. The standard note may be produced by an electric diaphragm buzzer (as in the Siemens-Barkhausen audiometer with a single frequency of about 800 cycles), a valve oscillator (for example, the Western Electric audiometer with a choice of eight frequencies), or a gramophone record (with pure or 'warbling' notes), together with a suitable attenuator, in each case.

With all the various types of audiometer, the reading is best approached by a series of progressive comparisons alternating on either side of the critical value. In general, experience indicates that most people find themselves able, after a little practice, to obtain fairly consistent results with even the simpler forms of audiometer, at any rate with noises which are more or less continuous. On the whole, masking results are easier to obtain than matching or equality values. In the United States, masking results are usually preferred, affording as they do a measure of the degree of 'deafening' or the raising of the threshold limit for the particular frequency or band of frequencies used.

CLICKER EXPERIMENTS ON NOISE MEASUREMENT.

In 1929 I made some rough experiments on noise measurement, by the aid of a flexed steel-strip 'clicker', such as is sometimes used by lecturers. The note of the clicker is high pitched and surprisingly penetrating, and can be heard in quiet surroundings nearly 1000 feet away. The masking range of audibility was determined under a variety of conditions. In an aeroplane cabin or near a pneumatic road breaker or a riveter the range shrinks to 2-3 ft., while near an aeroplane engine the range is only a few inches. On the somewhat doubtful assumption of the inverse square law, the clicker confirmed the fact that the interior of a tube train (75-80 db.) is appreciably louder than that of an express train travelling at about 60 m.p.h.—even in the corridor with some of the windows open (70 db.). It is, of course, common knowledge that it is difficult to converse and listen in a tube train, but not difficult in an ordinary train with the windows closed, particularly in a first-class carriage, with its more generous upholstery.

The cabin of an aeroplane in a cross-Channel flight was found to be at least a thousand times (30 db.) noisier than an express train, although the plywood cabin walls cut down the noise of the engine a hundred-fold (20 db.). The preference exercised by knowledgeable passengers for seats in the rear of the cabin rather than in the region of the side propellers was confirmed, there being some 10 decibels difference. It was found that the customary practice of aeroplane passengers of plugging their ears with cotton-wool resulted in a reduction of the noise experienced by about 10 decibels.

TUNING FORK MEASUREMENTS OF NOISE.

A very convenient and portable means of measuring noise has been suggested and used by Davis * at the National Physical Laboratory. A tuning fork is struck in some convenient standard manner—against the heel of the boot will do quite well, and no unusual care is necessary. The fork is then held with the flat of the prong towards the opening of the ear and as close as possible without actually touching. The time of striking the fork is noted, and the interval of time is observed until the loudness falls to the level of the surrounding noise. If desired, the time interval before the note of the fork is masked by the noise can also be measured. The rate of decay of the fork is calibrated in decibels

---

* NATURE, Jan. 11, 1930.

by a buzzer or other type of audiometer. As the decay of the loudness of a fork is practically logarithmic, the calibration curve of decibels against time is roughly linear. Readings are facilitated in practice if, as the fork is approaching the matching value, it is moved to and from the ear, so that its sound is alternately louder and softer than that of the noise.

A particular fork used by Davis had a frequency of 640 cycles per second. Its loudness when it was struck was about ninety db., and the rate of decay was about 1½ db. per second. Noises as high as 110 db. were measured by means of masking observations.

Davis has used the method for determining the loudness of a variety of noises over the range of hearing, and obtained results which, as will be seen from Table I., are in good agreement with audiometer measurements by American observers.

RELATION BETWEEN THE LOUDNESS VALUE AND THE MASKING VALUE OF NOISES.

As the masking effect of a noise is dependent on its composition, theoretically it is, in general, not possible to associate the loudness value of a noise (as determined either physically or by aural matching) and the masking value as determined aurally by one or other of the available audiometers. As a practical fact, however, it would appear that, for most of the ordinary complex and fairly continuous noises of everyday life, the loudness value exceeds the masking by a fairly constant difference, which tends to increase somewhat for louder noises, or for those of an intermittent staccato character.

For normal street and interior noises, the New York Noise Commission found that, on the average, the loudness value exceeded the medium-frequency masking value by about 15 db. For a very loud noise (90 db.), such as the intense cheering of a large crowd, it would appear from the Commission's Report, "City Noise", that the two values differed by 20 db. Davis in his tuning fork experiments found a like difference for a loudness of 110 db. He also deduces an approximately linear relation between masking and matching values for moderately loud noises.

In the case of measurements of aeroplane propeller noises of very high intensity made for the Aeronautical Research Noise Sub-Committee by the National Physical Laboratory, the two values differed by about 20-30 db., though it will be realised that measurements under such conditions are necessarily somewhat rough.

EXAMPLES OF NOISE MEASUREMENT.

Some simple illustrations of the measurement of everyday noises may be of service.

The loudness of speech ranges between about 40 db. and 60 db., an ordinary conversational tone being about 50 db. If, however, the lips of an average speaker are within half an inch of the ear of a person with normal hearing, the latter will receive the speech at a level of about 100 db. An average motor horn sounded about twenty feet away illustrates a loudness of about 80 db. Twins crying together are only 3 decibels louder than one crying alone! Another way of increasing a noise by 3 db. is for the observer to move 30 per cent nearer (that is, when in the open air); movement of another 20 per cent nearer (that is, halving the distance) would give a total gain of 6 db.

Fig. 4 shows a kind of 'noise thermometer' of common noises ranging up to 100 db.—a level which is unlikely to be exceeded in everyday experience. Some broad general groupings of noises are indicated on the left. Above 50 db. the scale is differentiated as containing in general those noises which we should do well to endeavour to moderate so far as it may be practicable to do so, and we can perhaps regard this figure as a kind of 'temperate' level on our noise thermometer.

Table I. contains a collection of loudness levels (rounded to the nearest 5 db.) of various noises as determined in Great Britain by the National Physical Laboratory, and in the United States mainly by the New York Noise Commission (the figure for the medium frequency test note being selected). Certain points of general interest are discussed below:

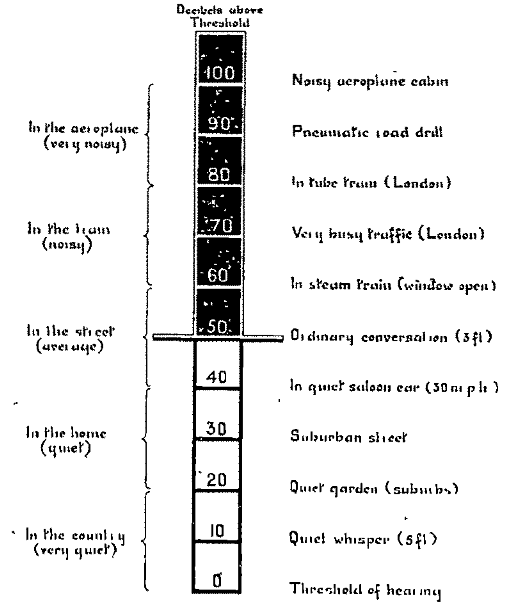

FIG. 4.—Loudness levels of common noises.

Table I. includes a variety of traffic noises both in London and New York, and, so far as it may be possible to draw a fair comparison, it would seem that a street in New York is on the average about 10 db. noisier than a like street in London. Although there are thoroughfares in London where at times a barking dog would not be heard 20 feet away, there are traffic centres in New York where, as the Commission has pointed out, a tiger could roar indefinitely without attracting the auditory attention of passers-by. It is stated that certain street corners in New York are normally noisier than anywhere so far discovered in the world; for example, the corner of Sixth Avenue and Thirty-fourth Street, which rejoices in three main streets, three tram-car lines, a double track line of the elevated railway, and the Subway (Underground). The arch sinner is the elevated railway, and nothing, I imagine, is less likely than that London will ever allow anything approximating to an overhead railway to override its streets.

The New York Commission found that the ebb and flow of noise from hour to hour closely parallels the density of the traffic, at any rate up to a figure of 50 vehicles per minute.

Some diminution of the traffic noise heard would naturally be expected in the higher stories of a building, but the effect is largely nullified if there are high buildings on both sides of the street. In such cases, even with 'sky-scrapers', appreciable relief only comes to the stories just above the first set-back. Wise travellers book bedrooms on the twentieth floor upwards in certain hotels in New York and Chicago.

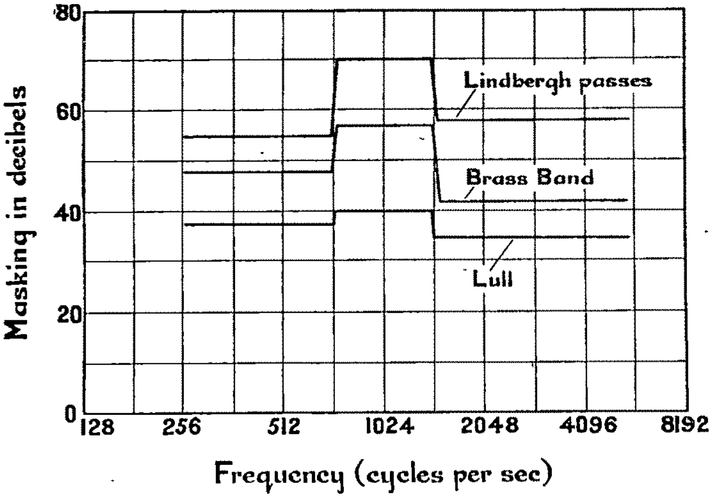

FIG 5.—Crowd noises measured 110 feet away.

Fig. 5, due to Galt, shows masking measurements of crowd noises obtained by the use of a 3-band warbler audiometer on the occasion of Lindbergh's arrival in New York after his Atlantic flight. The observers were on the fifth floor, about 110 feet from the street. The masking effects of the noise produced by the crowd's welcome as Lindbergh passed are pronounced—quite sufficient, in fact, to mask the sound of a brass band not many yards distant. It is clear that here is a quantitative method, as Mr. Galt remarks, by which footlight and other favourites of the public can periodically assess their popularity.

As regards the individual components of traffic noise, it would seem from the limited data available that British and American tram-cars do not on the average differ appreciably as regards noise. The same remark probably holds for motor cars. It is of interest to note quantitative evidence that a modern car at moderate speeds is quieter than a horse vehicle on a paved street.

Among the contributory factors to traffic noise are motor horns, into the noisiness and stridency of which an inquiry of a restricted character was undertaken in 1929 by the National Physical Laboratory on behalf of the Ministry of Transport. Observations were made in a closed chamber with heavily lagged walls. Both physical and aural methods of measuring noise were employed, cathode ray oscillograph records being also made of the average wave form. It appeared from the limited observations that stridency was bound up largely with sheer loudness, but that strong high-frequency components, strong unrelated notes, and any marked starting characteristics were among the probable contributory factors. It was not found possible to correlate stridency with wave form.

The New York Noise Commission arrived at much the same conclusions. It considers that horns with sound levels in excess of about 90 db. when heard 23 feet away are unnecessary and objectionable. It finds that complaints of stridency are unlikely to arise when fundamental frequencies lie between 200 cycles and 300 cycles, when the overtones are all harmonics of the fundamental and share the energy evenly, and when there is an absence of strong high frequencies.

As regards trains, the noise levels of express and suburban trains in England and America seem to be not unlike for a similar class of accommodation. The American method of dividing up Pullman sleeping cars partly by means of heavy curtains seems, despite its other drawbacks, to result in a noise level comparable with that of our own more secluded first-class sleeping berths. In such circumstances, however, much depends on other factors, such as the good fitting of doors and windows, which restrict noise admission.

With reference to underground railways, the New York Subway stands in a class apart for noise —as anyone who has travelled by it will testify. London 'tubes' appear to be at least 10 db. quieter, though questions of speed may come in.

Among the loudest things one is likely to encounter are the noises of riveting, pneumatic road drilling, steamship sirens, and printing presses. More untoward events are lions and the Niagara Falls, which can apparently roar equally loudly (85 db.). But the arch offender is the aeroplane engine at close quarters (110 db.). The noise in the cabins of aeroplanes in flight ranges between 80 db. and 110 db., according to the type of machine. The noise of the propeller is probably the dominant factor, though engine exhaust and general engine clatter run it close, and all three must be seen to if an improvement is to be apparent. In the view of the Aeronautical Research Noise Sub-Committee, there are, however, good prospects that the noise in aeroplane cabins will presently be substantially reduced (possibly to that of a railway train) by using propellers with lower tip speeds, providing more effective silencers on the exhausts, reducing engine clatter by enclosing the engines, and constructing cabins of double walls containing a suitable filler.

PROTECTION FROM NOISE.

The best way of securing protection from noise is to quieten it at its source. This is much more effective than trying to control it later. For example, machines may be enclosed, or better balanced, or better shaped, and mounted on insulating materials.

As regards traffic noise, a great deal of the more objectionable noise is due to vehicles which are ill-cared for and in bad condition or badly loaded. Indiscriminate horn blowing is not, I think, a characteristic British trait. Where there is considerable traffic noise, much can be done to add to the comfort of a building by creating sound shadows, and by architectural ingenuity in providing 'buffer' rooms, a recent example of which is afforded by the new headquarters of the British Broadcasting Corporation.

The protective shielding by buildings is well illustrated by the sylvan quietness of enclosed quadrangles, such as the Inns of Courts, which are in close proximity to noisy streets. The bedrooms opening on a hotel courtyard are usually much quieter than a room on the outside of the building, though sometimes the domestic quarters are so situated as to nullify the advantage.

There are two main practical methods for insulating an enclosure against air-borne noises: (*a*) By using single non-porous rigid walls or partitions. (*b*) By using multiple partitions as independent as possible and separated by air or some kind of loose filling.

In the case of the single rigid type of wall, the weight is the primary factor, the insulation value (in decibels) being proportional to the logarithm of the mass of the wall per square foot of area. Prisoners in the castle dungeons of old could not have been greatly troubled by air-borne sounds! Fig. 6 illustrates the measurements of Davis and Littler at the National Physical Laboratory. Their results, with those of Knudsen, the Bureau of Standards and others on single partitions, are summarised in Table II. for a medium frequency (512 cycles per second). The insulation values are in general rather less for low frequencies and rather more for high frequencies. As panels transmit sound mainly by diaphragm action, resonance effects may come into operation at low frequencies, but under normal conditions are probably of secondary importance.

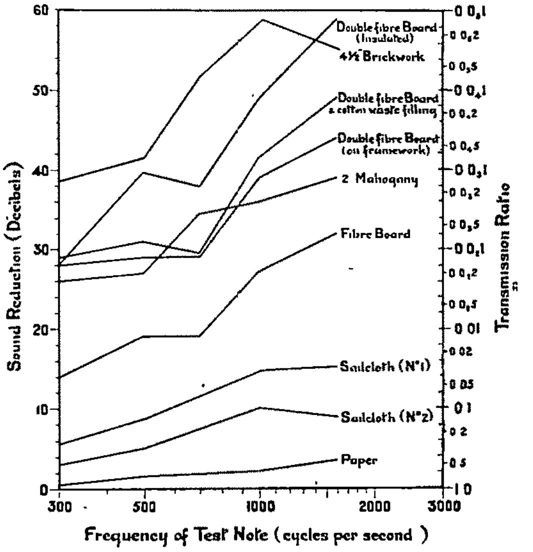

FIG. 6.—Insulating values of various materials for notes of different frequencies. (Davis and Littler.)

TABLE II.

SOUND INSULATION VALUES OF RIGID SINGLE PARTITIONS FOR AIR-BORNE SOUNDS.

Mass per sq. ft. of Wall Area.	Reduction of Sound in Decibels.
0·1 lb.	9
0·2	14
0·5	20
1	24
2	29
5	33
10	38
20	43
*40	48
60	51
100	54

* 4½ in. brick wall.

As a rough working rule, doubling the mass increases the insulation value by about five decibels, though resonance effects may spoil the relation.

In the case of porous flexible materials, Knudsen states that the insulating value is proportional to the mass of the wall per square foot of section rather than to its logarithm. Often a combination of the porous flexible material and the rigid dense partition is advantageous.

It may be here mentioned that for the stages of talking-film studios, insulation values of from 50 db. to 70 db. are aimed at according to the circumstances.

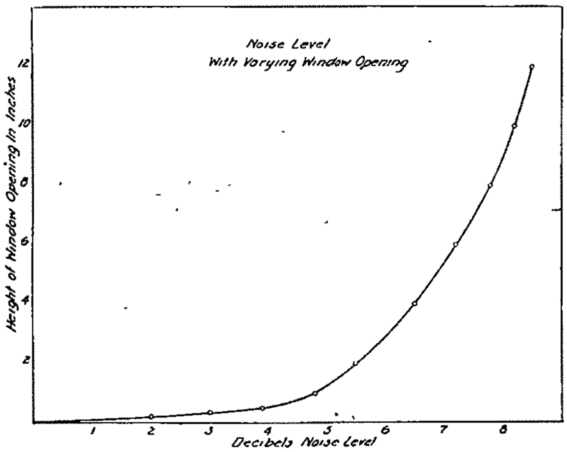

FIG. 7.

As regards multiple partitions, they should be wholly free of cross ties, that is, completely isolated from one another, if the combination is to be any better (as it may be) than one single partition of the same over-all thickness. Whether or not a loose filling material should be sandwiched between the panels is a matter for experiment, as such a filler may or may not be beneficial. On one hand, it may act as an absorbent and a damper of vibration, and on the other it may serve as a tie.

The question of protection from structure-borne noises is one to which it is hoped attention may be paid in the new Sound Laboratories which are to be erected at the National Physical Laboratory, as there is need for systematic experiment. Heterogeneity and discontinuity appear to be of value, and loose fillers may prevent the drumming of resonant panels or walls, which is often an accompaniment to such vibrations and may result in pronounced sound emission.

In many houses the windows are the chief offenders in admitting external noises. Sound-proof construction would be greatly simplified if windows could be abolished! This, of course, is not to be contemplated, but we can at any rate use substantial windows of thick glass. Opening a window even a little will, of course, largely nullify the benefit of noise shielding and absorbing devices. Within limits the amount of sound admitted by a crack or opening is proportional to its area. In the case of a door or window affording, say, 30 decibels insulation, a crack with an area 1/1000 of that of the door would admit as much sound as passes through the door or window.

Fig. 7 (due to Norris) shows the progressive increase in the noise level in a room when a window opening on to external noise was gradually opened. It will be noted that a small opening may produce a large effect.

Finally, considerable advantage may accrue in preventing noise which has gained entrance into a room from building up into a high level of reverberant sound by lining the walls and ceilings with absorbent materials. Certain banks and business houses in the City already employ the plan with advantage. I understand that many houses in New York line the roofs of their entrance porches with acoustic absorbent, deriving, it is stated, beneficial effects.

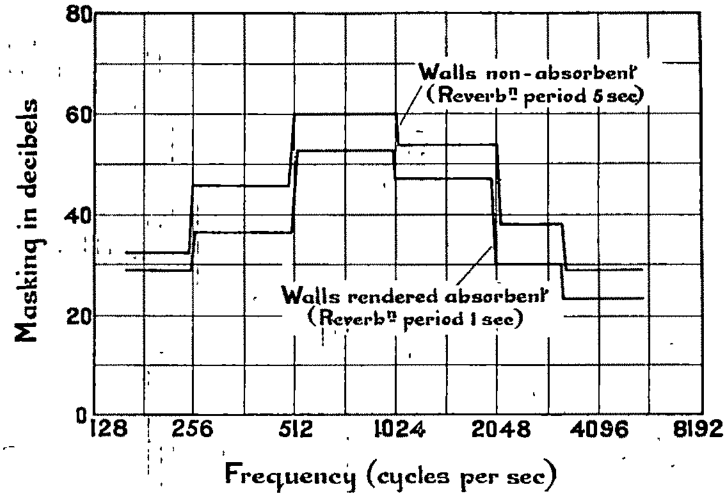

FIG. 8.—Room noises.

Fig. 8 (due to Galt) illustrates the effect on masking measurements in a room subjected to traffic noise of lining the walls with absorbent. As will be seen, the masking value was reduced by about seven decibels on the average, corresponding to a reduction in the reverberation period of from 5 sec. to 1 sec.

Printed in Great Britain by R. & R. CLARK, LIMITED, *Edinburgh.*

study will become possible. We welcome an announcement which appears in *Man* for June that the Salle de Travail d'Ethnologie juridique of the Faculty of Law of the University of Paris is prepared to act provisionally as a central bureau for the study of customary Oriental and tropical law, and to serve as a channel of intercommunication between those who are interested in such studies. For this purpose, the subject has been divided into eight divisions according to geographical areas, and a beginning has been made by the printing of a dictionary of Indonesian law with the assistance of the International Academic Union. The study of Indonesian law will be further served by existing institutions, the Adat Law Section of the Royal Batavian Society of Arts and Sciences at Batavia, founded in 1926, and the Adat Law Foundation at Leyden, which was established in 1917. An inquiry is to be instituted in the Philippines in the current year.
